Computer Networks

Jürgen Schönwälder

May 17, 2019

Abstract

This memo contains annotated slides for the course "Computer Networks". This is largely work in progress since annotating a large collection of slides is an effort that takes time.

Contents

I Introduction	4
Internet Concepts and Design Principles	5
Structure and Growth of the Internet	14
Internet Programming with Sockets	21
II Fundamental Concepts	37
Classification and Terminology	38
Communication Channels and Transmission Media	47
Media Access Control	58
Transmission Error Detection	69

HTTP 1.1 Methods	360
HTTP 1.1 Features	366
HTTP 2.0	375
XII Multimedia over the Internet	377
Voice over IP	378
Real-time Transport Protocol (RTP)	382
Session Initiation Protocol (SIP)	383
XIII Summary Tables	384

Part I Introduction

This part provides an introduction to core concepts of the Internet and it discusses how the Internet has grown to what it is today. This section also briefly reviews the socket application programming interface, which was already introduced in the course "Operating Systems".

Section 1: Internet Concepts and Design Principles

1 Internet Concepts and Design Principles

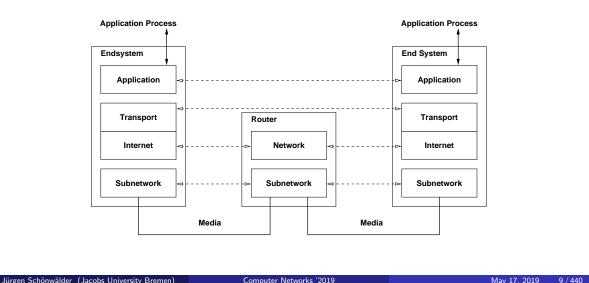

2 Structure and Growth of the Internet

3 Internet Programming with Sockets

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 8 / 440

Internet Model

The Internet uses a simple layered model.

- The most important layer is the *network layer* also called the *Internet layer*. It provides services that moves data packets from a source node to a destination node. Data packets may cross intermediate nodes called routers that take forwarding decisions in order to move the data packets closer to their destination. The data forwarding service provided by the Internet layer is unreliable. Data packets may get lost, they may get modified, or they may even get duplicated or replayed.
- The Internet layer uses the services of the *sub-network layer* to transmit data packets to the next node. There are many different sub-network technology and the Internet tries to make very few assumptions about the capabilities of the sub-networks.
- The second most important layer is the *transport layer*. It provides an end-to-end service, enabling communication between two applications located on different nodes. The transport layer provides different services. The most widely used services are a bidirectional reliable data stream service and an unreliable datagram service.
- The *application layer* supports certain types of applications (e.g., electronic mail, web pages, remote login). The application layer is often further decomposed into multiple layers but there is no strict architectural requirement how the application layer is structured for a given application type.

It is important to always be aware of which layer is being discussed. Students often get confused because they start to mix functions that reside in different layers together. Now that you have been warned, please always pay attention to (i) what a layer offers as a service to higher layers, (ii) what services a layer uses provided by lower layers, and (iii) what mechanisms are are internal to the realization of a layer. If you manage to keep things properly separated, then computer networking becomes simple.

Ideally, layers provide a certain functionality without exposing details how this is achieved. It is generally desirable to keep layers as much as possible independent of each other since this allows layers to be replaced. Of course, strict layer separation prohibits certain performance optimizations and hence in reality we often find situations where a layer assumes something about the internals of another layer (which is called a layer violation).

Note that the network layer, the transport layer, or even the application layer can serve as a sub-network. This makes the model recursive (but there are practical limits for the recursion depths in real-world networks since every recursion increases overhead and reduces network performance).

Internet Design Principles

• Connectivity is its own reward

Jürgen Schönwälder (Jacobs University Bremen)

- All functions which require knowledge of the state of end-to-end communication should be realized at the endpoints (end-to-end argument)
- There is no central instance which controls the Internet and which is able to turn it off
- Addresses should uniquely identify endpoints
- Intermediate systems should be stateless wherever possible
- Implementations should be liberal in what they accept and stringent in what they generate

Computer Networks '2019

May 17, 2019 10 / 440

• Keep it simple (when in doubt during design, choose the simplest solution)

The *end-to-end argument* is of special importance for the design of the Internet and it must be understood from the historic context. When the Internet was designed in the last century, the big global networks were telecommunication networks providing voice call services. These networks were designed to work with very simple and cheap telephones located at the edges of the network and all network functionally was provided inside of the network. Most telephones were even powered by the telecommunication network. The price for cheap and simple telephones was a complex and expensive technology inside of the network. The end-to-end argument was a disruptive idea at that time as it proposed to simplify the networking core as much as possible by moving all functionality that requires knowledge of the state of end-to-end communication to the endpoints. This assumes that endpoints are capable to take over functionality that was so far provided inside of the network. The big advantage of this approach is that the functionality needed in the core of a network gets simplified and to a large extend stateless, which makes it possible to build high-speed networking equipment at much lower prices since the devices do not need to keep state for all the applications using the network.

The design principle that addresses should be unique has lost value over time. Unique addresses have a big advantage for troubleshooting and debugging. However, the fast growth of the Internet encouraged people to reuse addresses. And nowadays, globally unique addresses are also considered problematic from a privacy perspective.

Internet Addresses

Jürgen Schönwälder (Jacobs University Bremen)

- Four byte IPv4 addresses are typically written as four decimal numbers separated by dots where every decimal number represents one byte (dotted quad notation). A typical example is the IPv4 address 192.0.2.1
- Sixteen byte IPv6 addresses are typically written as a sequence of hexadecimal numbers separated by colons (:) where every hexadecimal number represents two bytes
- Leading nulls in IPv6 addresses can be omitted and two consecutive colons can represent a sequence of nulls
- The IPv6 address 2001:00db8:0000:0000:0000:0000:0000 can be written as 2001:db8::1
- See RFC 5952 for the recommended representation of IPv6 addresses

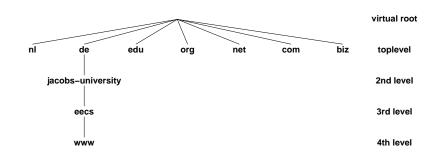

Computer Networks '2019

May 17, 2019 11 / 440

IP addresses are often split into a portion that identifies a certain network (the so called network prefix) and a portion that identifies a certain endpoint within a network. For example, the IPv4 address 192.0.2.1 may belong to the 192.0.2.1/24 network. The /24 suffix indicates that the first 24 bits of the address form the network prefix. Similarly, the 2001:db8::1 may belong to the 2001:db8::/32 network. The /32 suffix indicates that the first 32 bits of the address form the network prefix.

Internet Domain Names

Jürgen Schönwälder (Jacobs University Bremen)

- The Domain Name System (DNS) provides a distributed hierarchical name space which supports the delegation of name assignments
- DNS name resolution translates DNS names into one or more Internet addresses

Computer Networks '2019

May 17, 2019 12 / 440

Humans are much better in remembering names than addresses. We all can remember google.com but only very few people can remember the IP addresses used by Google. The domain name services is essentially a distributed directory that can be used to resolve domain names to IP addresses. The hierarchical structure of the domain name system allows to delegate authority over the different parts (called zones) of the global namespace.

Autonomous Systems

Jürgen Schönwälder (Jacobs University Bremen)

- The global Internet consists of a set of inter-connected autonomous systems
- An *autonomous system* (AS) is a set of routers and networks under the same administration
- Autonomous systems are identified by 32-bit numbers, called AS numbers (ASNs) (originally the number space was limited to 16-bit but this has been increased to 32-bit)
- IP packets are forwarded between autonomous systems over paths that are established by an *Exterior Gateway Protocol* (EGP)
- Within an autonomous system, IP packets are forwarded over paths that are established by an *Interior Gateway Protocol* (IGP)

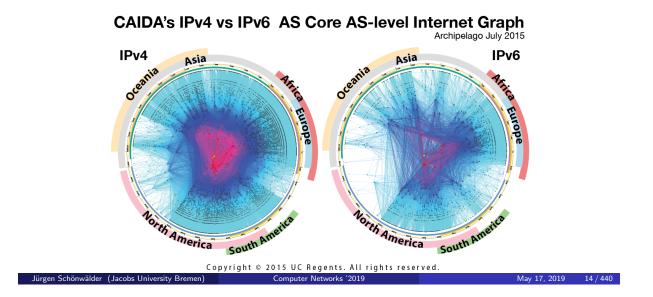

The Internet was designed from the very beginning as a network of networks that can quickly adopt to changes. The Internet is essentially a collection of autonomous networks (called autonomous systems) that choose to collaborate in order to provide connectivity and Internet services. As such, there is no central authority controlling the Internet. Given the importance that the Internet has gained, it is no surprise that various organizations try to obtain control over the Internet or services provided over the Internet.

Computer Networks '2019

May 17, 2019 13 / 440

Jacobs University receives Internet connectivity from the German national research and education network (NREN) called DFN. The autonomous system number (ASN) assigned to DFN is 680. ASNs are assigned by regional internet registries (RIRs). The RIR responsible for Europe is the Réseaux IP Européens Network Coordination Centre (RIPE NCC), an independent not-for-profit organization located in Amsterdam. The other four RIRs are the American Registry for Internet Numbers (ARIN), the Asia-Pacific Network Information Centre (APNIC), the Latin American and Caribbean Internet Addresses Registry (LACNIC), and the African Network Information Centre (AfriNIC).

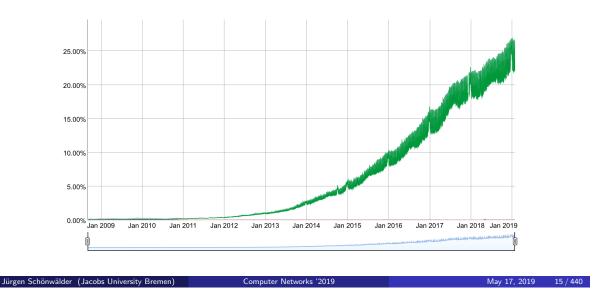

Autonomous Systems

The Center for Applied Internet Data Analysis (CAIDA) is collecting data about the structure of the Internet and occasionally producing visualizations that show the structure of the Internet. The graphs shown here plot the autonomous systems by using polar coordinates (radius, angle). For a given autonomous systems (AS), the angle is determined by the longitude of the AS and the radius is determined by the number of other ASes the AS is connected to (providing transit services).

 $radius(AS) = 1 - log\left(\frac{\text{transit.degree}(AS) + 1}{\text{maximum.transit.degree} + 1}\right)$ angle(AS) = longitude(AS)

Google IPv6 Adoption Statistics

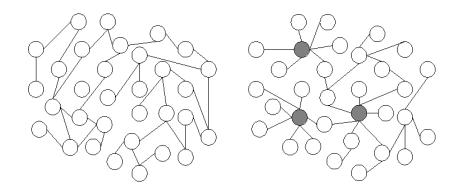

This plot shows the percentage of traffic Google has received over IPv6. The IPv6 protocol was designed in the 1990s but it took more than 20 years until it started to carry a noticeable amount of traffic. While the Internet is often associated with a fast evolution, there are also changes affecting core components that take a lot of time to get widely deployed.

One warning about statistics: It is of key importance to understand what has been measured and how and whether there is any bias in a dataset due to the way data was collected. For example, a common misinterpretation of the Google statistics is that they provide a good reflection of global IPv6 adoption. This is, however, not necessarily the case since Google services are not accessible in all countries and Google has strong competitors in some regions.

Internet – A Scale-free Network?

Jürgen Schönwälder (Jacobs University Bre

 Scale-free: The probability P(k) that a node in the network connects with k other nodes is roughly proportional to k^{-γ} for some parameter γ.

Computer Networks '2019

May 17, 2019 16 / 440

A scale-free network is a network whose degree distribution follows a power law. Examples are social networks, collaboration networks, or protein-protein interaction networks. Scale-free networks provide short paths between two random nodes and they are robust against random failures. However, they are sensitive to targeted attacks against nodes with a high degree (often called hubs).

Section 2: Structure and Growth of the Internet

1 Internet Concepts and Design Principles

2 Structure and Growth of the Internet

3 Internet Programming with Sockets

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 17 / 440

Evolution of Network Services

- 1970: private communication (email)
- 1980: discussion forums (usenet)
- 1985: software development and standardization (GNU)
- 1995: blogs, art, games, trading, searching (ebay, amazon)
- 1998: multimedia communication (rtp, sip, netflix)
- 2000: books and encyclopedia (wikipedia)
- 2005: social networks, video sharing (facebook, youtube)
- 2010: cloud computing, content delivery networks (akamai, amazon)
- 2015: voice-controlled personal assistants (amazon alexa, google home)
- 2020: ???

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

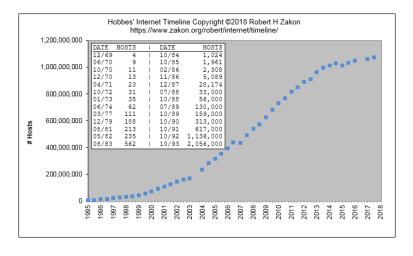

May 17, 2019 18 / 440

The evolution of services is very fast. The Internet makes it easy to try out new service ideas and it is possible that small startups become big players in a very short period of time. (But of course, the majoritu of all startups does not belong to the big winners.)

There is also an increasing amount of questionable uses of the Internet:

- many different forms of cyber crime
- collection and trading of personal profiles
- identity theft, doxing, cyberbullying or cyberharassment
- ransomware like WannaCry (2017) or CryptoLocker (2013)
- large-scale surveillance disclosure (Edward Snowden 2013)
- social bots spreading fake news and impacting the 2016 US and 2017 UK general elections
- ...

Growth of the Internet

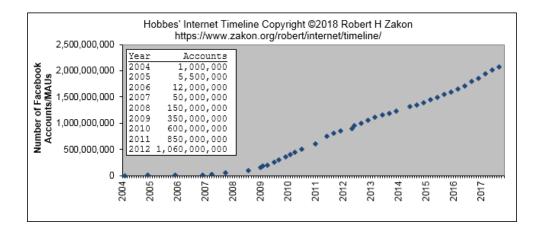

Jürgen Schönwälder (Jacobs University Bremen)

Computer Networks '2019

May 17, 2019 19 / 440

- How would you count the number of hosts on the Internet?
- Can we trust these numbers to be meaningful?
- Does it make sense to count lets say light bulbs?

Growth of Facebook

Jürgen Schönwälder (Jacobs University Bremen) C

Computer Networks '2019

May 17, 2019 20 / 440

- The number of facebook accounts is pretty easy to count.
- But how many accounts are active, how many are fake accounts?

Internet Exchange Points (Spring 2018)

- Internet Exchange Frankfurt/Germany (DE-CIX)
 - Connected networks: pprox 800
 - Average throughput (1 year): \approx 4.0*Tbps*
 - Maximum throughput (1 year): $\approx 6.0 Tbps$
 - Maximum transport capacity: $\approx 8 T b p s$
 - Total optical backbone capacity: \approx 48*Tbps*
 - 3 × 160 100 Gigabit-Ethernet ports
 - http://www.decix.de/
- Amsterdam Internet Exchange (AMS-IX)
 - http://www.ams-ix.net/
- London Internet Exchange (LINX)
 - https://www.linx.net/

Jürgen Schönwälder (Jacobs University Bremen)

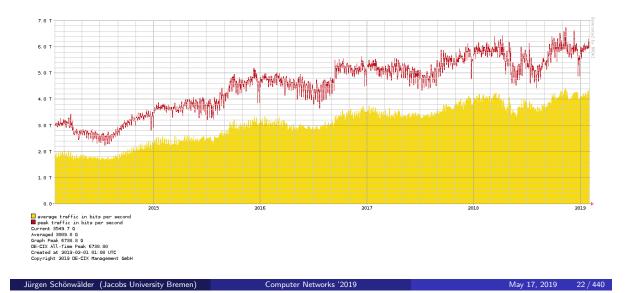

Internet Exchange Points (IXPs) are switching hubs where many Internet Service Providers (operating autonomous systems) connect in order to exchange Internet traffic. The biggest IXP in Germany is located in Frankfurt and operated by DE-CIX and it is also one of the biggest IXPs world-wide (in terms of traffic exchanged). The other two big European IXPs are the Amsterdam Internet Exchange (AMS-IX) and the London Internet Exchange (LINX).

May 17, 2019 21 / 440

Computer Networks '2019

Big IXPs are implemented as a highly distributed infrastructures in order to achieve a high degree of resilience against failures and attacks on the infrastructure.

DE-CIX Traffic (5 Years)

The traffic exchanged at IXPs keeps increasing. The DE-CIX peak and average traffic has doubled over the last five years. This forces IXPs to constantly increase their switching capacity. It is not clear whether there will be some saturation point. Note that not all traffic is exchanged through IXPs. It is a business decision whether ISPs peer with other ISPs through an IXP and via a bileratral setup. Hence, the traffic statistics of IXPs do not really tell you how Internet traffic in general is growing.

We often distinguish between an access network and a core network. Access networks connect enduser devices or end-user networks (home networks, small business networks) to an ISP and they may use technologies such as DSL lines, cable networks, fibre-to-the-home lines or mobile networks (3G, 4G, 5G). Access networks usually cover certain geographical regions. Aggregation networks take the data from access networks and aggregate it towards the core network, where highly aggregated traffic travels over usually longer-distance links. IXPs usually interconnect core or aggregation networks.

Networking Challenges

- Switching efficiency and energy efficiency
- Routing and fast convergence
- Security, trust, and key management
- Network measurements and automated network operations
- Ad-hoc networks and self-organizing networks
- Wireless sensor networks and the Internet of Things
- Delay and disruption tolerant networks
- High bandwidth and long delay networks
- Home networks, data center networks, access networks
- . . .

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 23 / 440

Availability of Internet connectivity has become an infrastructure requirement for the modern economy. Making networks (or computing systems in general) reliable and resilient is challenging. Big computing systems and computer networks consist of many (active and passive) components and failures of components is the norm rather than the exception. As a consequence, computer networks must be able to react to any disturbances efficiently, ideally fast enough such that applications do not notice any disturbances that are taking place.

Section 3: Internet Programming with Sockets

- 1 Internet Concepts and Design Principles
- 2 Structure and Growth of the Internet
- **3** Internet Programming with Sockets

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 24 / 440

Internet Programming with Sockets

- Sockets are abstract communication endpoints with a rather small number of associated function calls
- The socket API consists of

Jürgen Schönwälder (Jacobs University Bremen)

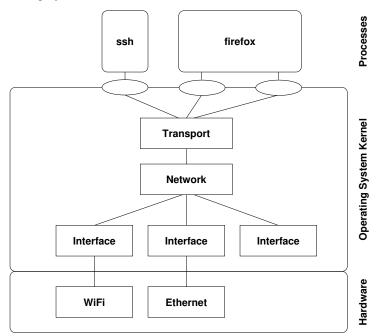

- address formats for various network protocol families
- functions to create, name, connect, destroy sockets
- functions to send and receive data
- functions to convert human readable names to addresses and vice versa
- functions to multiplex I/O on several sockets
- Sockets are the de-facto standard communication API provided by operating systems

Sockets provide an API for accessing the services provided by the transport layer, typically implemented in the operating system kernel.

Computer Networks '2019

May 17, 2019 25 / 440

The following figure provides a general overview how the Internet layers are implemented typically in general purpose operating systems.

Sockets are system call interfaces towards the transport layer. The transport layer uses services provided by the network layer. The underlying subnetwork layers (e.g., WiFi or Ethernet) are usually implemented in hardware. The operating system kernel provides a common abstraction for the subnetwork layer called a network interface or simply an interface. There can also be pure software interfaces that provide special services. A loopback software interface, for example, simply copies all data received from the network layer back to the network layer. The network layer in general exchanges data with multiple network interfaces.

Socket Types

- Stream sockets (SOCK_STREAM) represent bidirectional reliable communication endpoints
- Datagram sockets (SOCK_DGRAM) represent bidirectional unreliable communication endpoints
- Raw sockets (SOCK_RAW) represent endpoints which can send/receive interface layer datagrams
- Reliable delivered message sockets (SOCK_RDM) are datagram sockets with reliable datagram delivery
- Sequenced packet sockets (SOCK_SEQPACKET) are stream sockets which retain data block boundaries

Connection-Less Communication

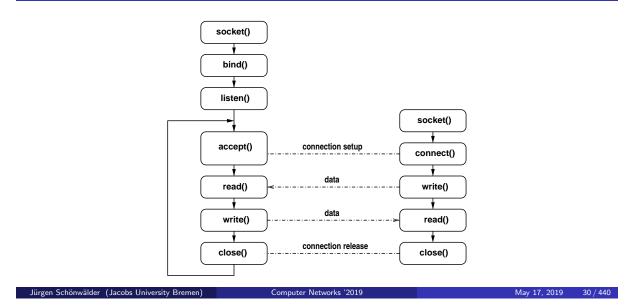

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 29 / 440

Connection-less communication can be very fast and efficient, in particular in situations when a server is used by many different clients or a client has to communicate with many different servers. Datagram sockets provide programmatic access to a connection-less communication service provided by the Internet. A possible downside of the Internet connection-less datagram service is that it only provides a best-effort service and hence applications must be able to deal with datagram losses, reorderings of datagrams, duplication of datagrams etc.

Connection-Oriented Communication

Connection-oriented communication requires to establish a connection before data can be exchanged and to teardown the connection when the data exchange has finished, which introduces a certain overhead. Stream sockets provide programmatic access to a connection-oriented service provided by the Internet. An advantage of the connection-oriented stream service is that the service will issues caused by datagram losses, reorderings of datagrams, or duplication of datagrams.

Most of the Internet traffic (in terms of data volume) is using connection-oriented communication services.

Multiplexing

Jürgen Schönwälder (Jacobs University Bremen)

```
#include <sys/select.h>
typedef ... fd_set;
FD_ZERO(fd_set *set);
FD_SET(int fd, fd_set *set);
FD_CLR(int fd, fd_set *set);
FD_ISSET(int fd, fd_set *set);
int select(int n, fd_set *readfds, fd_set *writefds,
           fd_set *exceptfds, struct timeval *timeout);
int pselect(int n, fd_set *readfds, fd_set *writefds,
           fd_set *exceptfds, struct timespec *timeout,
           sigset_t sigmask);
```

- select() works with arbitrary file descriptors
- select() frequently used to implement the main loop of event-driven programs Computer Networks '2019

May 17, 2019 37 / 440

Servers and clients often have to communicate with multiple endpoints concurrently and event-driven non-blocking I/O is an efficient way of implementing this. The select() system call can be used to implement portable event-loops. However, the select() system call is often not the most efficient solution and operating system kernels usually offer kernel specific solutions that scale more efficiently if an application has to manage a large number of endpoints. While it is an interesting exercise to implement your own generic event loop, it is highly advisable to avoid reinventing the wheel if your task is not to learn how to write your own event loop.

Programming frameworks often come with an event loop as part of the framework. If no programming framework providing an event loop is used, one may use dedicated libraries such as libevent.

Part II Fundamental Concepts

Before we can talk about how the Internet works, we need to introduce some basic terminology and ideas. Some of the material may look a bit dry since we introduce quite a few concepts and mechanisms and it may not be entirely clear yet why all of them are needed. Still, this background is important and having a common terminology and understanding of basic concepts will make it easier to communicate ideas clearly later on.

Section 4: Classification and Terminology

4 Classification and Terminology

- **5** Communication Channels and Transmission Media
- 6 Media Access Control
- 7 Transmission Error Detection
- 8 Sequence Numbers, Acknowledgements, Timer

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Flow Control and Congestion Control

Network Classifications

- Distance
 - Local area network, wide area network, personal area network, ...
- Topology
 - Star, ring, bus, line, tree, mesh, ...
- Transmission media
 - Wireless network, optical network,

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Purpose
 - Industrial control network, media distribution network, cloud network, access network, aggregation network, backbone network, vehicular network, ...
- Ownership
 - Home networks, national research networks, enterprise networks, government networks, community networks, . . .

May 17, 2019 41 / 440

Computer networks can be classified according to several criteria. The list of criteria on the slides is not necessarily complete. Try to think of other possible criteria.

Communication Modes

• Unicast — Single sender and a single receiver (1:1)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Multicast Single sender and multiple receivers (1:n)
- Concast Multiple senders and a single receiver (m:1)
- Multipeer Multiple senders and multiple receivers (m:n)
- Anycast Single sender and nearest receiver out of a group of receivers
- Broadcast Single sender and all receivers attached to a network
- Geocast Single sender and multiple receivers in a certain geographic region

We often focus on unicast communication. However, broadcast and multicast communication is a very important communication model in local area networks. Anycasting is widely deployed in today's Internet in order to provide fast access to popular content.

May 17, 2019 42 / 440

Concast communication is relatively rare and if it happens at large scale often associated with denial of service attacks where many senders try to overload a single receiver (the target of the attack).

Communication Protocol

Definition (communication protocol)

A *communication protocol* is a set of rules and message formats that govern the communication between communicating peers. A protocol defines

- the set of valid messages (syntax of messages) and
- the meaning of each message (semantics of messages).
- A protocol is necessary for any function that requires cooperation between communicating peers

Computer Networks '2019

- A protocol implements ideally a well-defined service
- It is often desirable to layer new protocols on already existing protocols in order reuse existing services

The notion of a communication protocol is central for this course. We use an informal definition here but there are of course ways to formalize the definition of message syntax as well as message semantics.

May 17, 2019 43 / 440

Many protocols are defined informally, although there is been research on formal protocol specifications. Informal protocol specifications are often incomplete or subject to interpretation. Standards developing organizations (SDOs) usually coordinate the development and the maintenance of protocol specifications. It is widely believed that open specifications and specifications that are not restricted by intellectual property rights are preferrable. The main bodies creating and maintaining network protocols are:

Internet Engineering Task Force (IETF)
 Internet protocols

Jürgen Schönwälder (Jacobs University Bremen)

- Institute of Electrical and Electronics Engineers (IEEE) local area networking technology (Ethernet, Wifi, Bluetooth, ...)
- Broadband Forum (BBF)
 ADSL/VDSL access network technology
- Metro Ethernet Forum (MEF) carrier Ethernet networks and services
- Open Networking Foundation (ONF) software-defined networking technology (OpenFlow)
- World Wide Web Consortium (W3C) world wide web standards
- 3rd Generation Partnership Project (3GPP) mobile networking technology (UMTS, LTE, 5G, ...)

Circuit vs. Packet Switching

- Circuit switching:
 - Communication starts by creating a (virtual) circuit between sender and receiver
 - Data is forwarded along the (virtual) circuit
 - Communication ends by removing the (virtual) circuit
 - Example: Traditional telecommunication networks
- Packet switching:
 - Data is carried in packets

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Every packet carries information identifying the destination
- Every packet is routed independently of other packets to its destination
- Example: Internet

The telephone network was designed as a circuit switched network. In the early days, human operators were plugging cables to establish a call. This was later automated but even with digital telecommunication networks, the notion of establishing a (virtual) circuit for every phone call remained. As a consequence, it was natural to charge for the length of the call (the time resources were allocated for the virtual circuit).

May 17, 2019 44 / 440

Packet switching ideas were developed in the 1960s, largely driven by the idea to build networks that could survive (nuclear) attacks. First prototype networks appeared in the late 1960s and early 1970s, leading to the development of the first Internet protocols during the 1970s.

Packet switching proved to be a far better match for data networking (compared to telecommunication networks designed to handle voice calls) since data networking usually involves the communication with many different endpoints.

During the 1990s, there was a big discussion whether packet switched networks, that rely on statistical multiplexing, could replace circuit switched networks, that allocate and reserve resources for every switched circuit. The argument was that resource reservation in circuit switched networks provides a means to guarantee a certain service quality. The counter argument was that similar quality can be achieved with statistical multiplexing by simply dimensioning the network capacity in such a way that it never operates at utilization levels where noticeable service quality degrations can appear.

Connection-oriented vs. Connection-less Services

- Connection-oriented:
 - Usage of a service starts by creating a connection
 - Data is exchanged within the context of a connection
 - Service usage ends by terminating the connection
 - State may be associated with connections (stateful)
 - Example: Fetching a web page on the Internet

• Connection-less:

Jürgen Schönwälder (Jacobs University Bremen)

- Service can be used immediately
- Usually no state maintained (stateless)
- Example: Internet name lookups

It is important to not confuse circuit vs. packet switching with connection-oriented vs. connection-less service. It is very well possible to realize connection-oriented services on a packet switched network. Most of the Internet traffic today is using connection-oriented services running over a packet switched network.

May 17, 2019 45 / 440

Computer Networks '2019

Data vs. Control vs. Management Plane

- Data Plane:
 - Concerned with the forwarding of data
 - Acting in the resolution of milliseconds to microseconds
 - Often implemented in hardware to achieve high data rates
- Control Plane:
 - Concerned with telling the data plane how to forward data
 - Acting in the resolution of seconds or sub-seconds
 - Traditionally implemented as part of routers and switches
 - Recent move to separate the control plane from the data plane

Computer Networks '2019

• Management Plane:

Jürgen Schönwälder (Jacobs University Bremen)

• Concerned with the configuration and monitoring of data and control planes

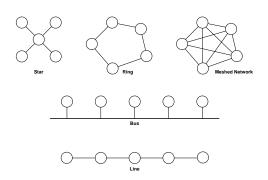

May 17, 2019 46 / 440

- Acting in the resolution of minutes or even much slower
- May involve humans in decision and control processes

Networking products developed in the 1990s and the early years of this century were usually bundling the data plane and the control plane together. A networking device such as a router did include both a hardware assisted data plane and a control plane implemented in software. The management plane was usually detached and implemented according to the needs of the network operator.

Work to separate the data plane and the control plane in data networks started in the early years of this century and the Ethane project at Stanford university finally led to the OpenFlow protocol, which lead to the architectural concept of Software Defined Networks, which largely builds on the idea to separate the control plane from the forwarding plane and thereby making the control plane freely programmable.

Topologies

• The *topology* of a network describes the way in which nodes attached to the network are interconnected

May 17, 2019 47 / 440

• Star:

- Nodes are directly connected to a central node

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Simple routing
- Good availability if central node is highly reliable
- Ring:
 - Nodes are connected to form a ring
 - Simple routing
 - Limited reliability, failures require reconfiguration
- Meshed Network:
 - Nodes are directly connected to all other nodes
 - Very good reliability
 - Requires $\frac{n(n-1)}{2}$ links for n nodes
- Bus:
 - Nodes are attached to a shared medium
 - Simple routing
 - Good availability if the bus is highly reliable
- Line:
 - Nodes are connected to form a line
 - Average reliability
 - Network position influences transmission delays

Line topologies are especially important in the case n = 2 (point to point links).

Structured Cabling

- Networks in office buildings are typically hierarchically structured:
 - Every floor has a (potentially complex) network segment
 - The floor network segments are connected by a backbone network
 - Multiple buildings are interconnected by connecting the backbone networks of the buildings
- Cabling infrastructure in the buildings should be usable for multiple purposes (telephone network, data communication network)
- Typical lifetimes:

Jürgen Schönwälder (Jacobs University Bremen)

- Network rooms and cable ways (20-40 years)
- Fibre wires (about 15 years)
- Copper wires (about 8 years)
- Cabling should survive 3 generations of active network components

The international standard ISO/IEC 11801 specifies structured cabling system suitable for a wide range of applications (telephony, data communication, building control systems, factory automation). It covers both balanced copper cabling and optical fibre cabling. The 3rd edition of ISO/IEC 11801 was released in November 2017.

May 17, 2019 49 / 440

Communication Channel Model

Jürgen Schönwälder (Jacobs University Bremen)

• Signals are in general modified during transmission, leading to transmission errors.

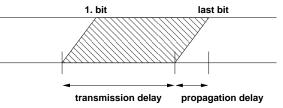

May 17, 2019 50 / 440

Computer Networks '2019

Channel Characteristics

Jürgen Schönwälder (Jacobs University Bremen)

- The *data rate* (bit rate) describes the data volume that can be transmitted per time interval (e.g., 100 Mbit/s)
- The *bit time* is the time needed to transmit a single bit (e.g., 1 microsecond for 1 Mbit/s)

- The *delay* is the time needed to transmit a message from the source to the sink. It consists of the *propagation delay* and the *transmission delay*
- The *bit error rate* is the probability of a bit being changed during transmission

To achieve high data rates, multiple bits can be transmitted concurrently (i.e., via coding system that can encode multiple bits into a code word).

Computer Networks '2019

May 17, 2019 51 / 440

We generally assume serial data transmission where a data word (e.g., an octet) is transmitted as an ordered sequence of bits. Serial data transmission has the benefit that it requires only a single channel (i.e., a single wire). The alternative, parallel data transmission, transmits all bits of a data word (e.g., an octet) concurrently. This, however, requires multiple channels (e.g., multiple wires).

Note that some coding schemes may use multiple multiple wires for efficiency reasons but from the outside we still consider such transmission systems to be serial.

Transmission Media Overview

- Copper wires:
 - Simple wires
 - Twisted pair
 - Coaxial cables
- Optical wires:
 - Fibre (multimode and single-mode)
- Air:
 - Radio waves
 - Micro waves
 - Infrared waves
 - Light waves

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 52 / 440

Simple Electrical Wires

• Simple two-wire open lines are the simplest transmission medium

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Adequate for connecting equipment up to 50 m apart using moderate bit rates
- The signal is typically a voltage or current level relative to some ground level
- Simple wires can easily experience crosstalk caused by capacitive coupling
- The open structure makes wires suspectible to pick-up noise signals from other electrical signal sources

May 17, 2019 53 / 440

Twisted Pairs

Jürgen Schönwälder (Jacobs University Bremen)

- A twisted pair consists of two insulated copper wires
- Twisting the wires in a helical form cancels out waves
- Unshielded twisted pair (UTP) of category 3 was the standard cabling up to 1988
- UTP category 5 and above are now widely used for wiring (less crosstalk, better signals over longer distances)

Computer Networks '2019

• Shielded twisted pair (STP) cables have an additional shield further reducing noise

May 17, 2019 54 / 440

Coaxial Cable

Jürgen Schönwälder (Jacobs University Bremen)

Insulation Outer conductor Protective plastic Core

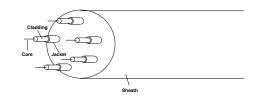

- Coax cables are shielded (less noise) and suffer less from attenuation
- Data rates of 500 mbps over several kilometers with a error probability of $10^{-7}\,$ achievable
- Widely used for cable television broadcast networks (which in some countries are heavily used for data communication today)

May 17, 2019 55 / 440

Computer Networks '2019

Fibre

Jürgen Schönwälder (Jacobs University Bremen)

- The glass core is surrounded by a glass cladding with a lower index of refraction to keep the light in the core
- Multimode fiber have a thick core (20-50 micrometer) and propagate light using continued refraction
- Single-mode fiber have a thin core (2-10 micrometer) which guides the light through the fiber

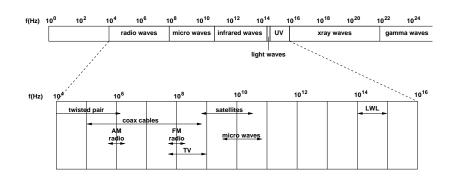

Computer Networks '2019

• High data rates, low error probability, thin, lightweight, immune to electromagnetic interference

May 17, 2019 56 / 440

Electromagnetic Spectrum

Jürgen Schönwälder (Jacobs University Bremen)

- Usage of most frequencies is controlled by legislation
- The Industrial/Scientific/Medical (ISM) band (2400-2484 MHz) can be used without special licenses

Computer Networks '2019

May 17, 2019 57 / 440

Transmission Impairments (1/2)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Attenuation:
 - The strength of a signal falls off with distance over any transmission medium
 - For guided media, attenuation is generally an exponential function of the distance
 - For unguided media, attenuation is a more complex function of distance and the makeup of the atmosphere
- Delay distortion:
 - Delay distortion occurs because the velocity of propagation of a signal through a guided medium varies with frequency
 - Various frequency components of a signal will arrive at the receiver at different times

May 17, 2019 58 / 440

Transmission Impairments (2/2)

- Noise
 - Thermal noise (white noise) is due to thermal agitation of electrons and is a function of temperature
 - Intermodulation noise can occur if signals at different frequencies share the same transmission medium
 - Crosstalk is an unwanted coupling between signal paths

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

• Impulse noise consists of irregular pulses or noise spikes of short duration and of relatively high amplitude

May 17, 2019 59 / 440

Section 6: Media Access Control

- Classification and Terminology
- **5** Communication Channels and Transmission Media

6 Media Access Control

- 7 Transmission Error Detection
- 8 Sequence Numbers, Acknowledgements, Timer

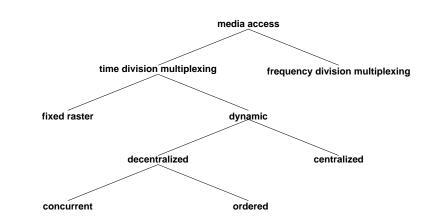

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- **9** Flow Control and Congestion Control
- **I** Layering and the OSI Reference Model

May 17, 2019 60 / 440

Media Access Control Overview

Jürgen Schönwälder (Jacobs University Bremen)

• Shared transmission media require coordinated access to the medium (media access control)

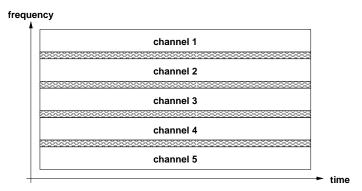

May 17, 2019 61 / 440

Computer Networks '2019

59

Frequency Division Multiplexing (FDM)

Jürgen Schönwälder (Jacobs University Bremen)

• Signals are carried simultaneously on the same medium by allocating to each signal a different frequency band

May 17, 2019 62 / 440

Computer Networks '2019

Wavelength Division Multiplexing (WDM)

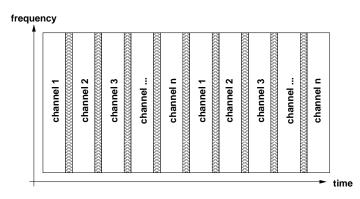

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Optical fibers carry multiple wavelength at the same time
- WDM can achieve very high data rates over a single optical fiber
- Dense WDM (DWDM) is a variation where the wavelengths are spaced close together, which results in an even larger number of channels.
- Theoretically, there is room for 1250 channels, each running at 10 Gbps, on a single fiber (= 12.5 Tbps).
- A single cable often bundles a number of fibers and for deployment or reasons, fibres are sometimes even bundled with power cables.

May 17, 2019 63 / 440

Time Division Multiplexing (TDM)

Jürgen Schönwälder (Jacobs University Bremen)

- Signals from a given sources are assigned to specific time slots
- Time slot assignment might be fixed (synchronous TDM) or dynamic (statistical TDM)

Computer Networks

May 17, 2019 64 / 440

Pure Aloha Station A: Station B: Station C: Station C: time • Developed in the 1970s at the University of Hawaii

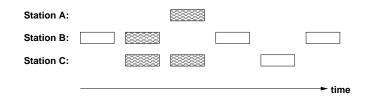

May 17, 2019 65 / 440

- Sender sends data as soon as data becomes available
- Collisions are detected by listening to the signal
- Retransmit after a random pause after a collision

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

• Not very efficient (pprox 18 % of the channel capacity)

Slotted Aloha

• Senders do not send immediately but wait for the beginning of a time slot

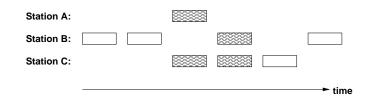

May 17, 2019 66 / 440

- Time slots may be advertised by short control signals
- Collisions only happen at the start of a transmission
- Avoids sequences of partially overlaying data blocks

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

• Slightly more efficient (\approx 37 % of the channel capacity)

Carrier Sense Multiple Access (CSMA)

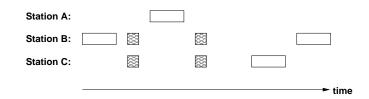

- Sense the media whether it is unused before starting a transmission
- Collisions are still possible (but less likely)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- 1-persistent CSMA: sender sends with probability 1
- p-persistent CSMA: sender sends with probability p
- non-persistent CSMA: sender waits for a random time period before it retries if the media is busy

May 17, 2019 67 / 440

CSMA with Collision Detection (CSMA-CD)

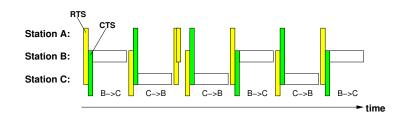

- Terminate the transmission as soon as a collision has been detected (and retry after some random delay)
- Let τ be the propagation delay between two stations with maximum distance
- Senders can be sure that they successfully acquired the medium after 2τ time units

May 17, 2019 68 / 440

• Used by the classic Ethernet developed at Xerox Parc

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

Multiple Access with Collision Avoidance (MACA)

• A station which is ready to send first sends a short RTS (ready to send) message to the receiver

Computer Networks '2019

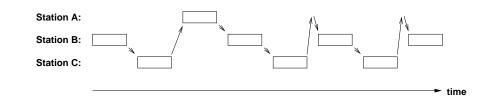

- The receiver responds with a short CTS (clear to send) message
- Stations who receive RTS or CTS must stay quiet

Jürgen Schönwälder (Jacobs University Bremen)

• Solves the hidden station and exposed station problem

May 17, 2019 69 / 440

Token Passing

- A token is a special bit pattern circulating between stations only the station holding the token is allowed to send data
- Token mechanisms naturally match physical ring topologies logical rings may be created on other physical topologies

May 17, 2019 70 / 440

• Care must be taken to handle lost or duplicate token

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

Section 7: Transmission Error Detection

- Classification and Terminology
- **5** Communication Channels and Transmission Media

May 17, 2019 71 / 440

Transmission Error Detection

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Data transmission often leads to transmission errors that affect one or more bits
- Simple parity bits can be added to code words to detect bit errors
- Parity bit schemes are not very strong in detecting errors which affect multiple bits
- Computation of error check codes must be efficient (in hardware and/or software)

May 17, 2019 72 / 440

Cyclic Redundancy Check (CRC)

- A bit sequence (bit block) $b_n b_{n-1} \dots b_1 b_0$ is represented as a polynomial $B(x) = b_n x^n + b_{n-1} x^{n-1} + \dots + b_1 x + b_0$
- Arithmetic operations:

Jürgen Schönwälder (Jacobs University Bremen)

$$0 + 0 = 1 + 1 = 0$$
 $1 + 0 = 0 + 1 = 1$

$$1 \cdot 1 = 1$$
 $0 \cdot 0 = 0 \cdot 1 = 1 \cdot 0 = 0$

• A generator polynomial $G(x) = g_r x^r + \ldots g_1 x + g_0$ with $g_r = 1$ and $g_0 = 1$ is agreed upon between the sender and the receiver

Computer Networks '2019

• The sender transmits $U(x) = x^r \cdot B(x) + t(x)$ with

$$t(x) = (x^r \cdot B(x)) \mod G(x)$$

May 17, 2019 73 / 440

Cyclic Redundancy Check (CRC)

- The receiver tests whether the polynomial corresponding to the received bit sequence can be divided by G(x) without a remainder
- Efficient hardware implementation possible using XOR gates and shift registers
- Only errors divisible by G(x) will go undetected
- Example:

Jürgen Schönwälder (Jacobs University Bremen)

- Generator polynomial G(x) = x³ + x² + 1 (corresponds to the bit sequence 1101)
- Message *M* = 1001 1010 (corresponds to the polynomial *B*(*x*) = *x*⁷ + *x*⁴ + *x*³ + *x*)

Choosing Generator Polynomials

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- G(x) detects all single-bit errors if G(x) has more than one non-zero term
- G(x) detects all double-bit errors, as long as G(x) has a factor with three terms
- G(x) detects any odd number of errors, as long as G(x) contains the factor (x+1)
- *G*(*x*) detects any burst errors for which the length of the burst is less than or equal to *r*
- G(x) detects a fraction of error bursts of length r + 1; the fraction equals to $1 2^{-(r-1)}$
- G(x) detects a fraction of error bursts of length greater than r + 1; the fraction equals to $1 2^{-r}$

May 17, 2019 77 / 440

Well-known Generator Polynomials

gen Schönwälder (Jacobs University Bremen)

- The HEC polynomial $G(x) = x^8 + x^2 + x + 1$ is used by the ATM cell header
- The CRC-16 polynomial $G(x) = x^{16} + x^{15} + x^2 + 1$ detects all single and double bit errors, all errors with an odd number of bits, all burst errors with 16 or less bits and more than 99% of all burst errors with 17 or more bits
- The CRC-CCITT polynomial $G(x) = x^{16} + x^{15} + x^5 + 1$ is used by the HDLC protocol

Computer Networks '2019

• The CRC-32 polynomial $G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$ is used by the IEEE 802 standards

May 17, 2019 78 / 440

Internet Checksum

```
uint16_t
checksum(uint16_t *buf, int count)
{
    uint32_t sum = 0;
    while (count--) {
        sum += *buf++;
        if (sum & Oxffff0000) {
            sum &= 0xffff;
            sum++;
        }
    }
    return ~(sum & Oxffff);
}
```

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 79/440

Internet Checksum Computation

data[] = dead cafe face (hexadecimal)

+	0000 dead	(data[0])	verification: +	0000 dead	(data[0])

Errors Affecting Complete Data Frames

- Despite bit errors, the following transmission errors can occur
 - Loss of complete data frames
 - Duplication of complete data frames

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

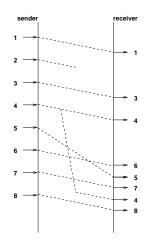

- Receipt of data frames that were never sent
- Reordering of data frames during transmission
- In addition, the sender must adapt its speed to the speed of the receiver (*end-to-end flow control*)
- Finally, the sender must react to congestion situations in the network (*congestion control*)

May 17, 2019 83 / 440

Sequence Numbers

- The sender assigns growing sequence numbers to all data frames
- A receiver can detect reordered or duplicated frames
- Loss of a frame can be determined if a missing frame cannot travel in the network anymore
- Sequence numbers can grow quickly on fast networks

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

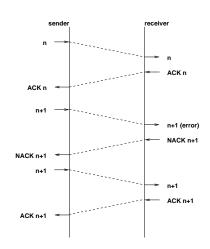

May 17, 2019 84 / 440

Acknowledgements

- Retransmit to handle errors
- A positive acknowledgement (ACK) is sent to inform the sender that the transmission of a frame was successful
- A negative acknowledgement (NACK) is sent to inform the sender that the transmission of a frame was unsuccessful
- Stop-and-wait protocol: a frame is only transmitted if the previous frame was been acknowledged

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

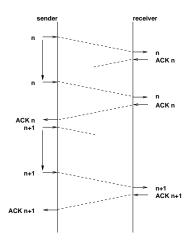

May 17, 2019 85 / 440

Timers

Jürgen Schönwälder (Jacobs University Bremen)

- Timer can be used to detect the loss of frames or acknowledgments
- A sender can use a timer to retransmit a frame if no acknowledgment has been received in time
- A receiver can use a timer to retransmit acknowledgments
- Problem: Timers must adapt to the current delay in the network

Flow Control

- Allow the sender to send multiple frames before waiting for acknowledgments
- Improves efficiency and overall delay
- Sender must not overflow the receiver
- The stream of frames should be smooth and not bursty
- Speed of the receiver can vary over time

Sliding Window Flow Control

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Sender and receiver agree on a window of the sequence number space
- The sender may only transmit frames whose sequence number falls into the sender's window
- Upon receipt of an acknowledgement, the sender's window is moved
- The receiver only accepts frames whose sequence numbers fall into the receiver's window
- Frames with increasing sequence number are delivered and the receiver window is moved.
- The size of the window controls the speed of the sender and must match the buffer capacity of the receiver

May 17, 2019 89 / 440

Sliding Window Implementation

- Implementation on the sender side:
 - SWS (send window size)
 - LAR (last ack received)
 - LFS (last frame send)
 - Invariant: LFS LAR + $1 \leq$ SWS
- Implementation on the receiver side:
 - RWS (receiver window size)
 - LFA (last frame acceptable)
 - NFE (next frame expected)
 - Invariant: LFA NFE + $1 \leq$ RWS

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 90 / 440

Congestion Control

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Flow control is used to adapt the speed of the sender to the speed of the receiver
- Congestion control is used to adapt the speed of the sender to the speed of the network
- Principles:
 - Sender and receiver reserve bandwidth and puffer capacity in the network
 - Intermediate systems drop frames under congestion and signal the event to the senders involved
 - Intermediate systems send control messages (choke packets) when congestion builds up to slow down senders

Layering Overview

Layering

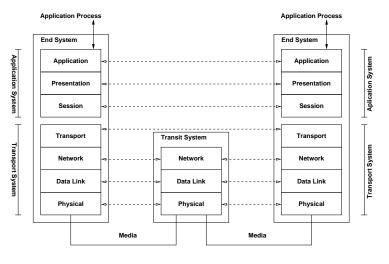

- Principles:
 - A layer provides a well defined service
 - A layer (service) is accessed via a service access point (SAP)
 - Multiple different protocols may implement the same service
 - Protocol data units (PDUs) are exchanged between peer entities
 - Service data units (SDUs) are exchanged between layers (services)
 - Every service access point (SAP) needs an addressing mechanism
- Advantages:
 - Information hiding and reuse
 - Independent evolution of layers
- Disadvantages:
 - Layering hinders certain performance optimizations
 - Tension between information-hiding (abstraction) and performance

Part III Local Area Networks (IEEE 802)

Local area networks connects computers within a limited area such as a university campus, an office building or a data center. Local area networking technology appeared in the 1970s and became commercially viable in the 1980s. The IEEE standardizes local area networking technology since 1980 under the project 802 (hence the name IEEE 802). IEEE organizes work in working groups, named after the project they belong to. The 802.11 working group, for example, defines standards for wireless networks while the 802.3 working group is responsible for the Ethernet standards.

Section 11: Local Area Networks Overview

- Local Area Networks Overview

- **IG** Wireless LAN (IEEE 802.11)
- **I** Logical Link Control (IEEE 802.2)

May 17, 2019 101 / 440

IEEE 802 Overview

Jürgen Schönwälder (Jacobs University Bremen)

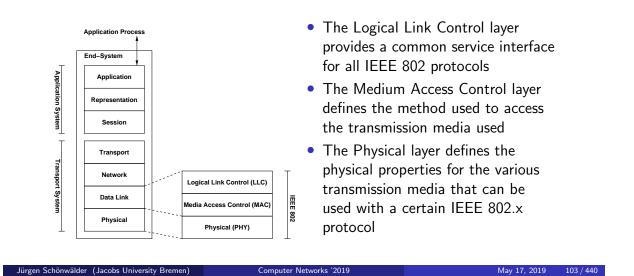

- IEEE 802 standards are developed since the early 1980s
- Dominating technology in local area networks (LANs)

There are many more working groups than shown on the slide. IEEE 802 has been successful by standardizing technology developed originally outside the IEEE even if the standards were competing against each other in the market. One benefit of this approach is that IEEE 802 did not have to select a technology and it "owns" the winners that the market selected. Ethernet technology (802.3) has been a tremendous success as has been wireless LAN technology (802.11). Bridging technology (802.1) has been extremely successful as well, even though bridging technology is challenged these days by disruptive new approaches replacing distributed control protocols with logically centralized control software, leading to so called software-defined networks (SDN).

Computer Networks '2019

May 17, 2019 102 / 440

IEEE 802 Layers in the OSI Model

The IEEE 802 standards cover the physical and data link layers of the OSI reference model. The data link layer is split into two parts, the media access control layer that is tied to the physical layer and the logical link control layer that aims at providing a common interface to higher layers in the protocol stack.

IEEE 802 Addresses

- IEEE 802 addresses (sometimes called MAC addresses or meanwhile also EUI-48 addresses) are 6 octets (48 bit) long
- The common notation is a sequence of hexadecimal numbers with the bytes separated from each other using colons or hyphens (00:D0:59:5C:03:8A or 00-D0-59-5C-03-8A)
- The highest bit indicates whether it is a *unicast* address (0) or a *multicast* address (1). The second highest bit indicates whether it is a *local* (1) or a *global* (0) address
- The *broadcast* address, which represents all stations within a broadcast domain, is FF-FF-FF-FF-FF-FF

May 17, 2019 104 / 440

• Globally unique addresses are created by vendors who apply for a number space delegation by the IEEE

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

Since number spaces are delegated to vendors, it is possible to associate a MAC address to the vendor. For example, a MAC address can reveal that a system on a network was built by Apple or that a printer was built by Konica. The address assignment happens usually relatively late in the production process. While MAC addresses were often stored in erasable programmable read-only memory (EPROMs) in the 1990s and hence not easy to modify, this has changed over the years and meanwhile it is often possible to modify MAC addresses. But note that networking technology generally assumes MAC addresses to be unique and hence you have to be careful with changing your MAC address.

Section 12: Ethernet (IEEE 802.3)

Local Area Networks Overview

12 Ethernet (IEEE 802.3)

- **I** Port Access Control (IEEE 802.1X)
- **I** Wireless LAN (IEEE 802.11)
- Logical Link Control (IEEE 802.2)

May 17, 2019 105 / 440

IEEE 802.3 (Ethernet)

Year	Achievement
1976	Original Ethernet paper published
1990	10 Mbps Ethernet over twisted pair (10BaseT)
1995	100 Mbps Ethernet
1998	1 Gbps Ethernet
2002	10 Gbps Ethernet
2010	100 Gbps Ethernet
2017	400 Gbps Ethernet
2020+	1.6 Tbps Ethernet (predicted)

• Link aggregation allows to "bundle" links, e.g., four 10 Gbps links can be bundled to perform like a single 40 Gbps link

May 17, 2019 106 / 440

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

The increase of the data rate is slowing down. This has technical reasons but also economic reasons. The number of systems that need a port speed of 1 Tbps or more is relatively small. Breaking the relatively high development costs down on a relatively small market makes the cost per port very high. It is thus often cheaper to bundle links running at lower speeds to obtain the desired data rates. 1 Tbps Ethernet may still happen at some point in time but the market first has to grow to make this a viable development effort.

IEEE 802.3 Frame Format

preamble	7 Byte		 Classic Ethernet used CSMA/CD and a shared bus
start-of-frame delimiter (SFD)	1 Byte	T	 Today's Ethernet uses a star topology with full durates links
destination MAC address	6 Byte		duplex links
source MAC address	6 Byte 2 Byte	yte	 Jumbo frames with sizes up to 9000 bytes can be used on dedicated links to improve throughput
data (network layer packet)	46-1500 Byte	64-1518 Byte	 Interface cards capable to segment large chunks of data (e.g., 64k) into a sequence of
padding (if required)	1		
frame check sequence (FCS)	4 Byte		frames (large segment offload, LSO) improve throughput on the sending side

The 802.3 frame format starts with a preamble and a start-of-frame delimiter so that the receiving station can synchronize with the sender and identity the start of the data frame. The fields of the data frame have the following meaning:

May 17, 2019 107 / 440

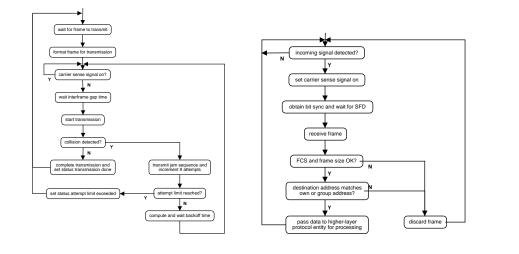

- Destination MAC Address: The MAC address of the intended recipient of the data frame.
- Source MAC Address: The MAC address of the originator of the data frame.
- Length / Type: The length of the frame (IEEE 802.3) or the type (Ethertype) of the data carried in the data frame. Type codes are larger than 1535 so that they do not collide with length values.
- Data: The payload carried in the data frame. If there is no type code, then the first bytes in the data field determine the type of the payload.
- Padding: Data may be padded in order to achieve a minimum frame size.
- Frame Check Sequence: A CRC-32 frame check sequence. The FCS is calculated over all data frame fields except the FCS itself.

The IEEE 802.3 frame format in a different notation:

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 109 / 440

Twisted pair cables of the category CAT5e and CAT6 are meanwhile pretty much standard. These cables support 1000BaseT and hence they can be used for 1 Gbps Ethernet.

10 Gbps Ethernet requires CAT7 twisted pair cables. Higher speeds almost always require optical fibers, since copper cables only work on very short distances (e.g., within a rack in a data center).

Bridged IEEE 802 Networks

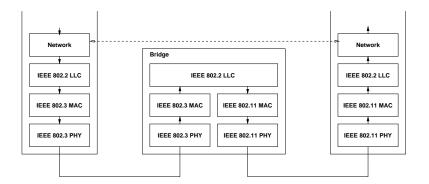

As networks grew, it became necessary to interconnect network segments. The different segments often use different IEEE 802 technologies. The solution was the introduction of bridges that "bridge network segments". In the market, bridges are often called switches. Bridges that bridge a wireless segment to an Ethernet segment are often called access points (and they may contain additional functionality not found in plain bridges).

A key features of Ethernet and bridging technology was that it was very easy to deploy (plug and play). Mass production made the technology very cheap as well. However, whenever a technology is plug and play, it opens a number of attack vectors that can be exploited to capture, redirect, or even rewrite traffic. And it a plug and play technology is usually also open to relatively simple denial of service attacks.

IEEE 802 Bridges

Jürgen Schönwälder (Jacobs University Bremen)

• Source Routing Bridges: Sender routes the frame through the bridged network

Computer Networks '2019

May 17, 2019 112 / 440

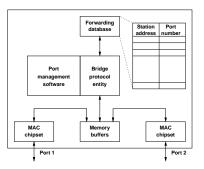

• Transparent Bridges: Bridges are transparent to senders and receivers

There was a large debate about source routing bridges versus transparent bridges when bridging technology was developed. Transparent bridges did win in the market since they reduce complexity at the connected stations and they were easier to deploy. In the following, we will only look at transparent bridges.

Nowadays, there is a movement to replace bridges with switches where an external controller guides the traffic flows through the network.

Transparent Bridges (IEEE 802.1D)

Jürgen Schönwälder (Jacobs University Bremen)

• Lookup an entry with a matching destination address in the forwarding database and forward the frame to the associated port.

Computer Networks '2019

• If no matching entry exists, forward the frame to all outgoing ports except the port from which the frame was received (flooding).

May 17, 2019 113 / 440

Backward Learning and Flooding

1. The forwarding database is initially empty.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- 2. Whenever a frame is received, add an entry to the forwarding database (if it does not yet exist) using the frame's source address and the incoming port number.
- 3. Reinitialize the timer attached to the forwarding base entry for the received frame.
- 4. Lookup the destination address in the forwarding database.
- 5. If found, forward the frame to the identified port. Otherwise, send the frame to all ports (except the one from which it was received).
- 6. Periodically remove entries from the forwarding table whose timer has expired.
- Aging of unsused entries reduces forwarding table size and allows bridges to adapt to topology changes.

May 17, 2019 114 / 440

• Backward learning and flooding requires a cycle free topology.

Backward learning is simple to implement and plug and play (as long as there is a cycle free topology). Flooding is, however, not scalable on very large topologies. The backward learning algorithm also opens the floor to a number of attacks.

- A malicious station may generate frames with a source address of another station in order to redirect traffic to the malicious station.
- A malicious station may generate frames with random source addresses causing the bridges to age out valid entries.

Spanning Tree

Jürgen Schönwälder (Jacobs University Bremen)

- 1. The root of the spanning tree is selected (root bridge). The root bridge is the bridge with the highest priority and the smallest bridge address.
- 2. The costs for all possible paths from the root bridge to the various ports on the bridges is computed (root path cost). Every bridge determines which root port is used to reach the root bridge at the lowest costs.
- 3. The designated bridge is determined for each segment. The designated bridge of a segment is the bridge which connects the segment to the root bridge with the lowest costs on its root port. The ports used to reach designated bridges are called designated ports.
- 4. All ports are blocked which are not designated ports or root ports. The resulting active topology is a spanning tree.

Computer Networks '2019

May 17, 2019 115 / 440

Port States

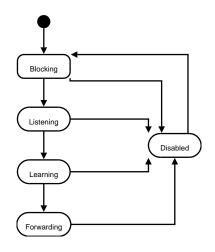

- Blocking: A port in the blocking state does not participate in frame forwarding.
- Listening: A port in the transitional listening state has been selected by the spanning tree protocol to participate in fame forwarding.
- Learning: A port in the transitional learning state is preparing to participate in frame forwarding.
- Forwarding: A port in the forwarding state forwards frames.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

• Disabled: A port in the disabled state does not participate in frame forwarding or the operation of spanning tree protocol.

Computer Networks '2019

- BPDUs are sent periodically over all ports (including blocked ports) to a special multicast address
- BPDUs are usually encapsulated in an LLC header (see below)
- Failure to transmit or deliver BPDUs may result in briding errors

May 17, 2019 118 / 440

Broadcast Domains

• A bridged LAN defines a single *broadcast domain*:

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- All frames send to the broadcast address are forwarded on all links in the bridged networks.
- Broadcast traffic can take a significant portion of the available bandwidth.
- Devices running not well-behaving applications can cause *broadcast storms*.
- Bridges may flood frames if the MAC address cannot be found in the forwarding table.
- It is desirable to reduce the size of broadcast domains in order to separate traffic in a large bridged LAN.
- Do not confuse a broadcast domain with a collision domain, i.e., segments on which media access collisions can occur.

It is important to understand the difference between a broadcast domain and a collision domain:

• A *broadcast domain* is a logical division of a computer network, in which all nodes can reach each other by broadcast at the data link layer.

May 17, 2019 119 / 440

• A *collision domain* is a network segment using a shared medium (or shared media connected through repeaters) where simultaneous data transmissions can collide with one another.

Examples for a collision domain are an IEEE 802.11 wireless segment or an IEEE 802.3 Ethernet segment with multiple stations attached to shared coaxial cable. An example of a broadcast domain is a simple bridged IEEE 802 network.

Note that bridges separate collision domains and this means that additional bridges can be used to reduce the likelihood of collisions, e.g., by splitting a long shared coaxial cable into smaller segments interconnected by a bridge.

To reducing a large broadcast domain, we can virtualize a local area network or we split a local area network in several local area networks interconnected by routers (i.e., on the networking layer).

Section 14: Virtual Local Area Networks (IEEE 802.1Q)

- Local Area Networks Overview
- Ethernet (IEEE 802.3)
- Bridges (IEEE 802.1)
- ☑ Virtual Local Area Networks (IEEE 802.1Q)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- **I** Port Access Control (IEEE 802.1X)
- **I** Wireless LAN (IEEE 802.11)
- **I** Logical Link Control (IEEE 802.2)

May 17, 2019 120 / 440

IEEE 802.1Q Virtual LANs

- VLANs provide a separation of logical LAN topologies from physical LAN topologies
- VLANs are identified by a VLAN identifier (1..4094)
- VLANs allow to separate the traffic on an IEEE 802 network
- A station only receives frames belonging to that VLANs it is a member of
- VLANs can reduce the network load:

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

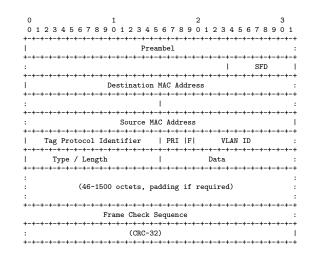

- 1. VLANs often cover only a certain part of the underlying physical topology
- 2. Frames that are targeted to all stations (broadcasts) will only be delivered to the stations connected to the VLAN
- Stations can be a member of multiple VLANs simultaneously (important for shared servers)

May 17, 2019 121 / 440

Virtual LANs are a common way to separate traffic on large local area networks. VLAN technology appeared in the 1990s but initially VLAN technology was not standardized and vendors had competing non-interoperable solutions. The 802.1Q standard has a limit of 4094 VLANs, which was considered a large number for typical enterprise and campus networks. Nowadays that are network deployments (e.g., cloud systems, access networks) where this limit causes problems.

IEEE 802.3 Tagged Frame Format

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 123 / 440

In order to carry a VLAN identifier, also called a VLAN tag, it was necessary to extend the IEEE 802.3 frame format. The new fields are:

- Tag Protocol Identifier: 16-bit value set to of 0x8100 used to identify a frame as a tagged frame.
- PRI: 3-bit priority code point used by IEEE 802.1p to differentiate different classes of service.
- F: bit to indicate that data frames are eligible to be dropped in the presence of congestion.
- VLAN ID: 12-bit unsigned number identifying the VLAN the data frame belongs to. The VLAN ID
 value 0x000 indicates that the tagged frame does not belong to a VLAN. (This may be used in
 situations where only priority tagging is needed.)

The extension required to change the maximum size of IEEE 802.3 frames in order to make space available for the VLAN header. Since oversized frames are rejected by hardware that is not VLAN aware, the deployment of VLANs had to start with making the bridges VLAN capable. Once the bridges were updated to support tagged frames, VLAN tagged frames were exchanged between VLAN-aware switches while stations were largely unaware of the existence of VLANs. Meanwhile, networking hardware is generally able to deal with VLAN tagged frames.

Network segments carrying traffic belonging to multiple VLANs are often called trunks.

VLAN Membership

Jürgen Schönwälder (Jacobs University Bremen)

- Bridge ports can be assigned to VLANs in different ways:
 - Ports are administratively assigned to VLANs (port-based VLANs)
 - MAC addresses are administratively assigned to VLANs (MAC address-based VLANs)
 - Frames are assigned to VLANs based on the payload contained in the frames (protocol-based VLANs)
 - Members of a certain multicast group are assigned to VLAN (multicast group VLANs)
- The Generic Attribute Registration Protocol (GARP) can (among other things) propagate VLAN membership information.

Computer Networks '2019

May 17, 2019 124 / 440

In practice, VLAN membership is usually port-based.

IEEE 802.1 Q-in-Q Tagged Frames (IEEE 802.1ad)

- With two tags, a theoretical limit of 4096 · 4096 = 16777216 different tags can be achieved (larger tag space)
- A tag stack allows bridges to easily modify the tags since bridges can easily "push" or "pop" tags
- A tag stack creates a mechanism for ISPs to encapsulate customer single-tagged 802.1Q traffic with a single outer tag; the outer tag is used to distinguish traffic from different customers
- Q-in-Q frames are convenient means of constructing layer 2 tunnels, or applying quality of service (QoS) policies
- 802.1ad is upward compatible with 802.1Q and although 802.1ad is limited to two tags, there is no ceiling in the standard allowing for future growth

May 17, 2019 125 / 440

• Double tagging is relatively easy to add to existing products

Jürgen Schönwälder (Jacobs University Bremen)

VLANs are quite common in corporate networks and they are getting increasingly used in home networks. Furthermore, access networks operated by Internet service providers are moving towards IEEE 802 technology. In order to connect for example a home office network using VLANs to a corporate network using VLANs via an Internet service provider network using IEEE 802 technology, it is necessary to carry VLAN tagged frames inside of VLAN tagged frames.

IEEE 802.1X Port Access Control

- Port-based network access control grants access to a switch port based on the identity of the connected machine.
- The components involved in 802.1X:

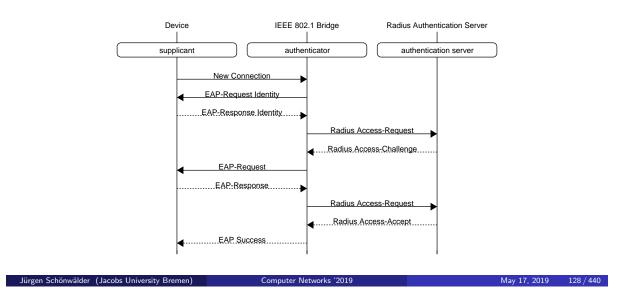

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- The *supplicant* runs on a machine connecting to a bridge and provides authentication information.
- The *authenticator* runs on a bridge and enforces authentication decisions.
- The *authentication server* is a (logically) centralized component which provides authentication decisions (usually via RADIUS).
- The authentication exchange uses the Extensible Authentication Protocol (EAP).
- IEEE 802.1X is becoming increasingly popular as a roaming solution for IEEE 802.11 wireless networks.

IEEE 802.1X provides a mechanism to securely and automatically join a network. Using IEEE 802.1X is much better for regular network access than other network access systems that attempt to redirect web traffic to web-based login pages (so called captive portals).

May 17, 2019 127 / 440

IEEE 802.1X Sequence Diagram

The Education Roaming (eduroam) network is an international roaming service for users in research, higher education and further education. It provides researchers, teachers, and students easy and secure network access when visiting an institution other than their own. The eduroam architecture is largely based on IEEE 802.1X, the Extensible Authentication Protocol (EAP), and RADIUS as the authentication protocol. For details, see the discussion in RFC 7593 [43].

• Very widely used wireless local area network (WLAN).

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- As a consequence, very cheap equipment (base stations, interface cards).
- Wired equivalent privacy (WEP) was a disaster (at least for those who believe a wire is secure).
- Recommended is WPA-2 (Wifi Protected Access), in particular in combination with 802.1X and EAP-TLS.

May 17, 2019 130 / 440

IEEE 802.11 2.4 GHz Channels

While there are several channels in the 2.4 GHz frequency range, it is important to choose them with care since neighboring channels overlap. Channel 6, for example, is centered at 2.437 GHz but uses the frequency range 2.426-2.448 GHz, which are also used by other nearby channels. Hence, there are only a few non-overlapping channels.

IEEE 802.11 Frame Types

- Data Frames: Carrying "useful" payloads
- Control Frames: Facilitate the exchange of data frames
 - Ready-to-send (RTS) and Clear-to-send (CTS) frames

Computer Networks '2019

IEEE Logical Link Control Header

- The LLC header follows the MAC frame header (but it is not always used)
- DSAP = Destination Service Access Point
- SSAP = Source Service Access Point

Jürgen Schönwälder (Jacobs University Bremen)

• Control = Various control bits, may indicate subsequent header

The LLC layer runs on top of the media specific media access control layer and it provides a common service interface for the networking layer. While the LLC layer is from an architectural point of view highly desirable, it is not commonly used on IEEE 802.3 Ethernet networks. It is, however, used on IEEE 802.11 wireless networks.

Computer Networks '2019

May 17, 2019 135 / 440

IEEE Logical Link Control SNAP Header (8-bit Control)

- The LLC header may be followed by the Subnetwork Access Protocol (SNAP) header (if indicated by the Control field)
- The Organizational Unit Identifier (OUI) identifies an organization defining Protocol ID values
- The Protocol ID identifies the protocol in the following payload

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

• If the OUI is 0x000000, the Protocol ID contains an Ethernet type value

May 17, 2019 136 / 440

Part IV Internet Network Layer

The Internet network layer provides a packet-oriented connection-less data exchange function. It has been designed to interconnect networks and it forms the basis of the global Internet. The main service provided by the Internet network layer is the delivery of packets from an arbitrary source interface to an arbitrary destination interface (or a set of destination addresses in the case of multicasts) in the Internet. For this to work, the Internet layer has to find paths, it has to deal with changes and errors, and it has to deal with some issues caused by crossing different types of subnetworks.

Section 18: Concepts and Terminology

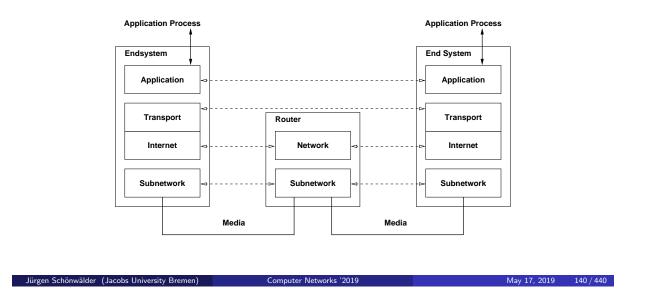

Concepts and Terminology

Internet Protocol Version 6

20 Internet Protocol Version 4

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 139/440

Internet Reference Model

The Internet reference model is less detailed compared to the OSI reference model, but there are similarities.

- The Internet layer roughly corresponds to the OSI network layer.
- The Transport layer roughly corresponds to the OSI transport layer.

The subnetwork layer below the Internet layer is mostly seen as a black box. The idea is that the Internet layer can function over a large number of very different subnetwork layers. There are, however, a number of suggestions for designers of subnetwork layers, see [20]. Note that it will be possible to run the Internet layer over a subnetwork that is itself an Internet layer or a transport layer (this recursion leads to what networking people call tunnels).

The application layer is not broken into separate layers by the architectural model, leaving it to designers of application protocols to define how many application layer internal layers they want to have. A common trend is to divide the application layer into a secure session layer, an application protocol layer, and a content layer. But there are no strict rules and application layer designers have the freedom to do whatever is considered the best solution.

Terminology (1/2)

- A node is a device which implements an Internet Protocol (such as IPv4 or IPv6).
- A router is a node that forwards IP packets not addressed to itself.
- A *host* is any node which is not a router.
- A *link* is a communication channel below the IP layer which allows nodes to communicate with each other (e.g., an Ethernet).
- The *neighbors* is the set of all nodes attached to the same link.
- An *interface* is a node's attachement to a link.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

• An *IP address* identifies an interface or a set of interfaces.

Note that a link connecting neighboring nodes can be simple or complex. A simple cable connecting exactly two nodes would be an example of a very simple link. An example for a much more complex link would be a large bridged IEEE 802 campus network involving several virtual LANs and integrating different transmission medias (e.g., fiber segments, twisted pair cobber wire segments, wireless segments).

May 17, 2019 141 / 440

Terminology (2/2)

Jürgen Schönwälder (Jacobs University Bremen)

- An *IP prefix* is the initial part of an IP address identifying an IP network. The IP prefix is commonly defined by the number of the initial bits of an IP address that are identifying an IP network, the so called *prefix length*.
- An *interface identifier* is the portion of an IP address that identifies an interface in a certain IP network.
- An *IP packet* is a bit sequence consisting of an IP header and the payload.

Computer Networks '2019

- The *link MTU* is the maximum transmission unit, i.e., maximum packet size in octets, that can be conveyed over a link.
- The *path MTU* is the the minimum link MTU of all the links in a path between a source node and a destination node.

The MTU for an Ethernet link is usually 1500 octets (bytes). If Ethernet is used together with LLC and SNAP, the MTU becomes 1492 octets (bytes). IEEE 802.11 has an MTU of 2304 octets (bytes) without security. Link security protocols like WPA2 consume additional octets (bytes).

May 17, 2019 142 / 440

Internet Address / Prefix Assignment

rgen Schönwälder (Jacobs University Bremen)

- Manual: A network administrator assigns an IP prefix manually to an interface.
- System: A networking stack automatically assigns a prefix to an interface (e.g., 127.0.0.1/8 or ::1/128 for a loopback interface).
- Stateless automatic configuration: A networking stack automatically calculates and assigns an IP prefix (e.g., deriving an interface identifier from a lower-layer address and combining it with a learned prefix).
- Stateful automatic configuration: A networking stack obtains an prefix from a service providing IP addresses on request (e.g., DHCP).
- Temporary addresses: A networking stack generates temporary addresses from a know prefix in order to enhance privacy.

Computer Networks '2019

There are additional address assignment techniques for specific purposes. Some examples:

• Derived addresses: A networking stack obtains an address or prefix from another valid address or prefix. This may be used in order to support address family translations.

May 17, 2019 143 / 440

• Cryptographic addresses: A networking stack generates an IP address from a cryptographic hash of a node's public key.

Jacobs University's IP Networks

Jürgen Schönwälder (Jacobs University Bremen)

- Jacobs University currently uses the global IPv4 address blocks 212.201.44.0/22 and 212.201.48.0/23. How many IPv4 addresses can be used in these two address spaces?
- 212.201.44.0/22: $2^{32-22} 2 = 2^{10} 2 = 1022$ 212.201.48.0/23: $2^{32-23} - 2 = 2^9 - 2 = 510$
- Jacobs University currently uses the global IPv6 address block 2001:638:709::/48. How many IPv6 addresses can be used?
- 2001:638:709::/48: $2^{128-48} 2 = 2^{80} 2$ which is 1208925819614629174706174.
- If you equally distribute the addresses over the campus area $(30 \cdot 10^4 m^2)$, what is the space covered per address?

Computer Networks '2019

May 17, 2019 144 / 440

Internet Network Layer Protocols

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- IPv6:
 - The *Internet Protocol version 6* (IPv6) provides for transmitting datagrams from sources to destinations using 16 byte IPv6 addresses
 - The *Internet Control Message Protocol version 6* (ICMPv6) is used for IPv6 error reporting, testing, auto-configuration and address resolution
- IPv4:
 - The *Internet Protocol version 4* (IPv4) provides for transmitting datagrams from sources to destinations using 4 byte IPv4 addresses
 - The Internet Control Message Protocol version 4 (ICMPv4) is used for IPv4 error reporting and testing
 - The Address Resolution Protocol (ARP) maps IPv4 addresses to IEEE 802 addresses

May 17, 2019 145 / 440

IP Forwarding

Jürgen Schönwälder (Jacobs University Bremen)

- IP addresses can be devided into a part which identifies a network (the network prefix) and a part which identifies an interface of a node within that network (the interface identifier).
- The *forwarding table* realizes a mapping of the network prefix to the next node (next hop) closer to the destination and the local interface used to reach the next node.
- For every IP packet, the entry in the forwarding table with the longest matching prefix for the destination address has to be found (longest prefix match).

Computer Networks '2019

• A default forwarding table entry (if it exists) uses a zero-length prefix, that is either 0.0.0.0/0 (IPv4) or ::/0 (IPv6).

May 17, 2019 146 / 440

IP Forwarding Table Management

Jürgen Schönwälder (Jacobs University Bremen)

- Entries of the IP forwarding table may be created by different entities:
 - Manual: A network administrator creates entries in the IP forwarding table manually.
 - System: A networking stack automatically creates forwarding entries (e.g., when assigning a prefix to a network interface).
 - Automatic Configuration Protocols: Protocols discovering valid prefixes or obtaining IP addresses and prefixes dynamically from a pool may create suitable IP forwarding table entries.
 - Routing Protocols: Distributed routing protocols create and maintain one or more routing tables that these routing tables feed data into the IP forwarding table.

May 17, 2019 147 / 440

• Some implementations support multiple forwarding tables that can be selected by certain packet properties.

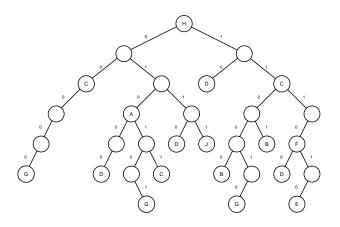

The terminology is often very imprecise here. People often call the forwarding table a routing table. However, people familiar with routing protocols tend to make a clear difference between the forwarding table that is actually used to forward traffic and the routing table(s) maintained by routing protocol implementations.

Computer Networks '2019

Modern routing protocol implementations usually support multiple routing protocols and they provide control mechanisms that can be used to select which entries of the various routing tables propagate to other routing tables and the forwarding table. On modern modular hardware-assisted routers, the forwarding table content is often distributed to the various line cards, with the routing protocol implementations running on a central processor, detached from the line cards forwarding traffic in hardware.

Longest Prefix Match: Binary Trie

Jürgen Schönwälder (Jacobs University Bremen)

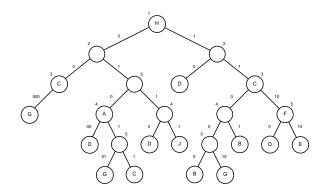

Computer Networks '2019

• A binary trie is the representation of the binary prefixes in a tree.

May 17, 2019 148 / 440

Longest Prefix Match: Path Compressed Trie

Jürgen Schönwälder (Jacobs University Bremen)

- A path compressed trie is obtained by collapsing all one-way branch nodes.
- The number attached to nodes indicates the next (absolute) bit to inspect.

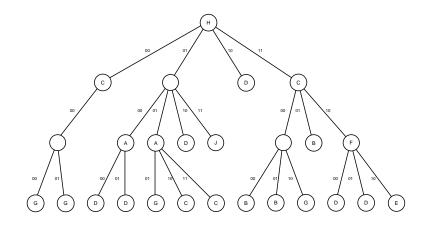

Computer Networks

• While walking down the tree, you verify in each step that the prefix still matches the prefix stored at each node.

May 17, 2019

149 / 440

Longest Prefix Match: Two-bit stride multibit Trie

Computer Networks '2019

• A two-bit multibit trie reduces the number of memory accesses.

Jürgen Schönwälder (Jacobs University Bremen)

Section 19: Internet Protocol Version 6

Concepts and Terminology

Internet Protocol Version 6

20 Internet Protocol Version 4

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 151/440

IPv6 Interface Identifier

- Interface identifiers in IPv6 unicast addresses are used to uniquely indentify interfaces on a link.
- For unicast addresses, except those that start with binary 000, interface identifiers are generally required to be 64 bits long.
- Combination of the interface identifier with a network prefix leads to an IPv6 address.
- Link local unicast addresses have the prefix fe80::/10.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Interface identifier may be obtained from an IEEE 802 MAC address using a modified EUI-64 format, but this has privacy issues.
- Alternatively, it is possible to use temporary interface identifiers that keep changing.

May 17, 2019 152 / 440

Modified EUI-64 Format

0 0	1 1 5 6	3 3 1 2	4 7	
+	+	 mmmmmmmm mmmmmmmm	+ mmmmmmmm	
+		+	+	
10	1 1	3 3	414	61

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Modified EUI-64 format can be obtained from IEEE 802 MAC addresses.
- Warning: Ipv6 addresses derived from MAC addresses can be used to track mobile nodes used in different networks.
- Solution: Temporary addresses with interface identifiers based on time-varying random bit strings and relatively short lifetimes.

On Linux, the command to manage IP addresses is called ip addr. You can use the -6 option to make it IPv6 specific.

May 17, 2019 153 / 440

```
$ ip -6 addr
1
   1: lo: <LOOPBACK,UP,LOWER_UP> mtu 65536 state UNKNOWN qlen 1
2
       inet6 ::1/128 scope host
3
           valid_lft forever preferred_lft forever
   2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 state UP qlen 1000
\mathbf{5}
       inet6 2001:638:709:3000::3a/64 scope global
6
           valid_lft forever preferred_lft forever

```

IPv6 Multicast Addresses

Address	Description
ff02::1	All nodes on the local link.
ff02::2	All routers on the local link.
ff02::3	All hosts on the local link.
ff02::1:2	All DHCP servers and relay agents on a local link.
ff02::fb	All multicast DNS servers on a local link.

• IPv6 multicast addresses use the prefix ff00::/8.

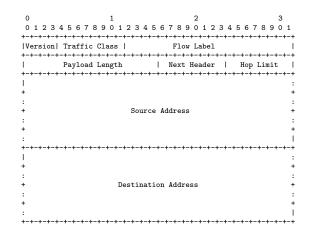

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- The addresses listed above are some of the well-known multicast addresses.
- Applications can, of course, allocate additional multicast addresses.

IPv6 uses multicast addresses in situations where IPv4 used broadcast addresses. This has certain advantages. For example, a request to find link local routers can be multicasted to all routers instead of sending a broadcast to all nodes.

May 17, 2019 154 / 440

IPv6 Packet Format (RFC 8200)

May 17, 2019 155 / 440

The IPv6 packet format is defined in RFC 8200 [11]. The packet fields have the following meaning:

• Version: 4-bit Internet Protocol version number (= 6).

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Traffic Class: 8-bit Traffic Class field. Used to carry Differentiated Services code points and Explicit Congestion Notification bits.
- Flow Label: 20-bit flow label. Can be used to tag IPv6 packets that belong to a flow. For details, see RFC 6437 [2].
- Payload Length: Length of the IPv6 payload, i.e., the rest of the packet following this IPv6 header, in octets.
- Next Header: 8-bit selector identifying the type of header immediately following the IPv6 header.
- Hop Limit: 8-bit unsigned integer, decremented by 1 by each node that forwards the packet. When
 forwarding, the packet is discarded if Hop Limit was zero when received or is decremented to zero.
- Source Address: 128-bit address of the originator of the packet.
- Destination Address: 128-bit address of the intended recipient of the packet.

Note that this is a header with a fixed size, there are no optional elements in the header itself.

The hop-limit field can be used to trace routes to hosts:

- Send an ICMPv6 Echo Request messages with increasing hop-limit values starting with one.
- A router counting the hop-limit down to zero will send a time exceeded ICMPv6 error message.
- The final destination will send an ICMPv6 Echo Reply message.

IPv6 Extension Header

- All IPv6 header extensions and options are carried in a header daisy chain.
 - Hop-by-Hop Options Extension Header (HO)
 - Destination Options Extension Header (DO)
 - Routing Extension Header (RH)
 - Fragment Extension Header (FH)
 - Authentication Extension Header (AH)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Encapsulating Security Payload Extension Header (ESP)
- Link MTUs must be at least 1280 octets and only the sender is allowed to fragment packets.

The basic packet forwarding functionality provided by the IPv6 header can be extended by using extension headers or a chain of extension headers.

• Hop-by-Hop Options Extension Header (HO): Options that need to be examined by all devices on the path.

May 17, 2019 156 / 440

- Destination Options Extension Header (DO): Options that need to examined only by the destination of the packet.
- Routing Extension Header (RH): Used to direct a packet to one or more intermediate nodes before being sent to its destination
- Fragment Extension Header (FH): Used to send packets that are larger than the path MTU; only the originator of a packet is allowed to fragment the packet.
- Authentication Extension Header (AH): Authenticates the originator of a packet and ensures data integrity by using a hash function and a secret shared key. A sequence number can protect the IP packet's contents against replay attacks.
- Encapsulating Security Payload Extension Header (ESP): Authenticates the originator of a packet and ensures data integrity by using a hash functions and a secret shared key. Confidentiality is provided by encrypting portions of IP packets.

The general idea is that extension headers are used rarely. In fact, on some routing platforms, packets with extension headers are processed in software while packets without extension headers are processed entirely in hardware.

IPv6 Forwarding

- IPv6 packets are forwarded using the longest prefix match algorithm.
- IPv6 addresses have relatively long prefixes, which allows network operators to achieve better address aggregation, which reduces the number of forwarding table entries needed in the backbone infrastructure.
- Due to the length of the prefixes, it is crucial to use a longest prefix match algorithm whose complexity does not dependent on the number of entries in the forwarding table or the average prefix length.
- Due to better aggregation possibilities, IPv6 forwarding tables can be expected to be shorter than IPv4 forwarding tables

On a Linux system, it is possible to look at the IPv6 forwarding table using the ip -6 route show command. The ip -6 route get command can be used to query the IPv6 forwarding table for the forwarding entry that would be used for a given address. The ip -6 route add and ip -6 route del commands can be used to add or remove forwarding table entries. For all command options (and there are many), look at ip -6 route help.

May 17, 2019 157 / 440

Computer Networks '2019

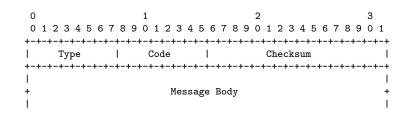

Here is an example demonstrating how to use the ip -6 route command:

1 \$ ip -6 route

Jürgen Schönwälder (Jacobs University Bremen)

- 2 2001:638:709:3000::/64 dev eth0 proto kernel metric 256 pref medium
- 3 fe80::/64 dev eth0 proto kernel metric 256 pref medium
- 4 default via 2001:638:709:3000::1 dev eth0 metric 1024 mtu 1472 pref medium
- 5 \$ sudo ip route add 2001:638:709:bad::/64 via 2001:638:709:3000::1 dev eth0
- $_6$ \$ ip -6 route
- 7 2001:638:709:bad::/64 via 2001:638:709:3000::1 dev eth0 metric 1024 pref medium
- 8 2001:638:709:3000::/64 dev eth0 proto kernel metric 256 pref medium
- 9 fe80::/64 dev eth0 proto kernel metric 256 pref medium
- 10 default via 2001:638:709:3000::1 dev eth0 metric 1024 mtu 1472 pref medium
- \$ sudo ip route del 2001:638:709:bad::/64
- 12 **\$ ip -6 route**
- 13 2001:638:709:3000::/64 dev eth0 proto kernel metric 256 pref medium
- 14 fe80::/64 dev eth0 proto kernel metric 256 pref medium
- 15 default via 2001:638:709:3000::1 dev eth0 metric 1024 mtu 1472 pref medium

IPv6 Error Handling (ICMPv6) (RFC 4443)

- The Internet Control Message Protocol Version 6 (ICMPv6) is used
 - to report error situations,
 - to run diagnostic tests,

- to auto-configure IPv6 nodes, and
- to supports the resolution of IPv6 addresses to link-layer addresses.

Jürgen Schönwälder (Jacobs University Bremen)	Computer Networks '2019

May 17, 2019 158 / 440

The ICMPv6 protocol is defined in RFC 4443 [7]. It uses a generic header that is followed by a message type specific message body. The fields of the generic ICMPv6 header are:

- Type: The type field indicates the type of ICMPv6 message.
- Code: The code field provides further details about the message type and the value spaces is scoped by the type field.
- Checksum: The checksum field is used to detect corruption in the ICMPv6 header and parts of the IPv6 header preceding the ICMPv6 header.

Some of the allocated type values are listed in the following table:

Туре	Description	
1	Destination Unreachable	RFC 4443
2	Packet Too Big	RFC 4443
3	Time Exceeded	RFC 4443
4	Parameter Problem	RFC 4443
128	Echo Request	RFC 4443
129	Echo Reply	RFC 4443
133	Router Solicitation	RFC 4861
134	Router Advertisement	RFC 4861
135	Neighbor Solicitation	RFC 4861
136	Neighbor Advertisement	RFC 4861

The following code values are used by a Destination Unreachable ICMPv6 message:

Code	Description
0	No route to destination
1	Communication with destination administratively prohibited
2	Beyond scope of source address
3	Address unreachable
4	Port unreachable
5	Source address failed ingress/egress policy
6	Reject route to destination

IPv6 Neighbor Discovery (RFC 4861)

- Discovery of the routers attached to a link.
- Discovery of the prefixes used on a link.
- Discovery of parameters such as the link MTU or the hop limit for outgoing packets.
- Automatic configuration of IPv6 addresses.

Jürgen Schönwälder (Jacobs University Bremen)

- Resolution of IPv6 addresses to link-layer addresses.
- Determination of next-hop addresses for IPv6 destination addresses.
- Detection of unreachable nodes which are attached to the same link.
- Detection of conflicts during address generation.
- Discovery of better alternatives to forward packets.

An IPv6 router may send periodically a Router Advertisement ICMPv6 message to the all nodes multicast address in order to announce its existence and to announce a prefix that is valid on a link. Nodes may also request that routers identify themselves by sending a Router Solicitation message to the all routers multicast address.

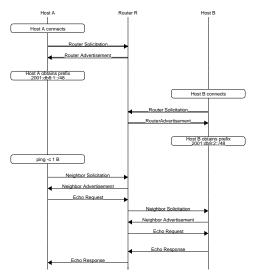

Computer Networks '2019

May 17, 2019 159 / 440

An IPv6 node may send a Neighbor Solicitations ICMPv6 message to the solicited-node multicast address in order to obtain the link-layer address of a target address contained in the IPv6 message body. A node responds by sending a Neighbor Advertisement message to the all nodes multicast address which adds the link-layer address to the target address in the message body.

Nodes generally cache neighborhood information and information about advertised routers and prefixes. On a Linux system, it is possible to look at the neighbor cache using the ip -6 neigh show command. Additional sub-commands can be used to add or delete neighbor cache entries. See ip -6 neigh help for more details.

The following time sequence diagram shows the usage of router and neighbor discovery messages.

IPv6 over IEEE 802.3 (RFC 2464)

- Frames containing IPv6 packets are identified by the value 0x86dd in the IEEE 802.3 type field.
- The link MTU is 1500 bytes, which corresponds to the IEEE 802.3 maximum frame size of 1500 byte.
- The mapping of IPv6 addresses to IEEE 802.3 addresses is table driven. Entries in so called address translation tables can be either statically configured or dynamically learned using the neighbor discovery protocol.
- IPv6 over IEEE 802.3 does not use IEEE LLC encapsulation.

IPv6 packets are easily sent over IEEE 802.3 links. RFC 2464 [8] allocates a suitable type code for the IEEE 802.3 length/type field.

May 17, 2019 1<u>60 / 440</u>

IPv6 multicast addresses are mapped to IEEE 802.3 multicast addresses. Note that the mapping potentially maps multiple IPv6 multicast addresses to the same IEEE 802.3 multicast address.

A router solicitation / advertisement exchange may look as follows:

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

```
{ eth-dst(all-router) eth-src(A) eth-type(ipv6)
  { ipv6-src(A) ipv6-dst(all-router) ipv6-next(icmpv6) ipv6-hop-limit(255)
    { icmpv6-type(133) icmpv6-code(0) }}
{ eth-dst(all-nodes) eth-src(R) eth-type(ipv6)
  { ipv6-src(R) ipv6-dst(all-nodes) ipv6-next(icmpv6) ipv6-hop-limit(255)
    { icmpv6-type(134) icmpv6-code(0) { ... }}}
The ICMPv6 echo request / response packets may look as follows:
{ eth-dst(R) eth-src(A) eth-type(ipv6)
  { ipv6-src(A) ipv6-dst(B) ipv6-next(icmpv6) ipv6-hop-limit(42)
    { icmpv6-type(128) icmpv6-code(0) }}
{ eth-dst(B) eth-src(R) eth-type(ipv6)
  { ipv6-src(A) ipv6-dst(B) ipv6-next(icmpv6) ipv6-hop-limit(41)
    { icmpv6-type(128) icmpv6-code(0) }}
{ eth-dst(R) eth-src(B) eth-type(ipv6)
  { ipv6-src(B) ipv6-dst(A) ipv6-next(icmpv6) ipv6-hop-count(42)
    { icmpv6-type(129) icmpv6-code(0) }}
```

```
{ eth-dst(A) eth-src(R) eth-type(ipv6)
  { ipv6-src(B) ipv6-dst(A) ipv6-next(icmpv6) ipv6-hop-count(41)
      { icmpv6-type(129) icmpv6-code(0) }}
```

Note that the hop limit has to be 255, IPv6 packets with a lower hop limit will be ignored. This ensures that it is impossible to route advertisements packets originating from remote hosts into a link.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 162 / 440

The IPv4 packet format is defined in RFC 791 [35]. The packet fields have the following meaning:

- Version: 4-bit Internet Protocol version number (= 4)
- IHL: 4-bit Internet Header Length in 32-bit words
- Type of Service: 8-bit Type of Service field. Used to carry Differentiated Services code points and Explicit Congestion Notification bits.
- Total Length: 16-bit total length of the packet in octets, including the IPv4 header and the data.
- Identification: 16-bit identification field used by the receiver to reassemble fragments.
- Flags: 3-bit control flags, including Don't Fragment (DF) and More Fragments (MF).
- Fragment Offset: 13-bit Fragment Offset indicates where a fragment belongs. The offset is measured in units of 8 octets (64 bits).
- Time to Live: 8-bit unsigned integer hop count field, decremented by 1 by each node that forwards the packet. When forwarding, the packet is discarded if Time to Live was zero when received or is decremented to zero.
- Protocol: 8-bit selector identifying the type of header immediately following the IPv4 header.
- Header Checksum: 16-bit checksum computed over the header. Since it includes fields that are modified by routers, it must be recomputed by every hop on a path.
- Source Address: 32-bit address of the originator of the packet.
- Destination Address: 32-bit address of the intended recipient of the packet.
- Options: Variable length list of header options.
- Padding: Data to align the header to a 32-bit boundary.

IPv4 Error Handling (ICMPv4)

- The Internet Control Message Protocol (ICMP) is used to inform nodes about problems encountered while forwarding IP packets.
 - Echo Request/Reply messages are used to test connectivity.
 - Unreachable Destination messages are used to report why a destination is not reachable.
 - Redirect messages are used to inform the sender of a better (shorter) path.
- Can be used to trace routes to hosts:
 - Send messages with increasing TTL starting with one and interpret the ICMP response message.
 - Pack additional data into the request to measure latency.
- ICMPv4 is an integral part of IPv4 (even though it is a different protocol).

The ICMPv6 protocol is defined in RFC 792 [34]. It uses a generic header that is followed by a message

- type specific message body. The fields of the generic ICMPv4 header are:
 - Type: The type field indicates the type of ICMPv4 message.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

• Code: The code field provides further details about the message type and the value spaces is scoped by the type field.

May 17, 2019 163 / 440

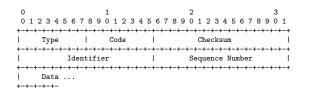

• Checksum: The checksum field is used to detect corruption in the ICMPv4 header and parts of the IPv4 header preceding the ICMPv4 header.

Some of the allocated type values are listed in the following table:

Туре	Description	
0	Echo Reply	RFC 792
3	Destination Unreachable	RFC 792
4	Source Quench	RFC 792
5	Redirect	RFC 792
8	Echo	RFC 792
9	Router Advertisement	RFC 1256
10	Router Selection	RFC 1256
11	Time Exceeded	RFC 792
12	Parameter Problem	RFC 792
13	Timestamp	RFC 792
14	Timestamp Reply	RFC 792

ICMPv4 Echo Request/Reply

Jürgen Schönwälder (Jacobs University Bremen)

• The ICMP echo request message (type = 8, code = 0) asks the destination node to return an echo reply message (type = 0, code = 0).

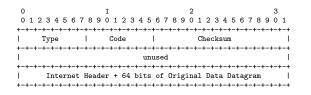

May 17, 2019 164 / 440

• The Identifier and Sequence Number fields are used to correlate incoming replies with outstanding requests.

Computer Networks '2019

• The data field may contain any additional data.

ICMPv4 Unreachable Destinations

- The Type field has the value 3 for all unreachable destination messages.
- The Code field indicates why a certain destination is not reachable.
- The data field contains the beginning of the packet which caused the ICMP unreachable destination message.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 165 / 440

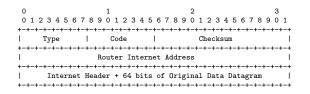

Unreachable destination codes:

_

Code	Description
0	Network Unreachable
1	Host Unreachable
2	Protocol Unreachable
3	Port Unreachable
4	Fragmentation Needed and Don't Fragment was Set
5	Source Route Failed
6	Destination Network Unknown
7	Destination Host Unknown
8	Source Host Isolated
9	Communication with Destination Network is Administratively Prohibited
10	Communication with Destination Host is Administratively Prohibited
11	Destination Network Unreachable for Type of Service
12	Destination Host Unreachable for Type of Service
13	Communication Administratively Prohibited
14	Host Precedence Violation
15	Precedence cutoff in effect

Note that some unreachable destination messages are crucial for the Internet to function correctly. It is therefore crucial that delivery of unreachable destination messages is not generally administratively blocked.

ICMPv4 Redirect

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- The Type field has the value 5 for redirect messages.
- The Code field indicates which type of packets should be redirected.
- The Router Internet Address field identifies the IP router to which packets should be redirected.
- The data field contains the beginning of the packet which caused the ICMP redirect message.

Redirect codes:

Code	Description
0	Redirect datagrams for the Network
1	Redirect datagrams for the Host
2	Redirect datagrams for the Type of Service and Network
3	Redirect datagrams for the Type of Service and Host

May 17, 2019 166 / 440

Note that redirect messages may be somewhat "dangerous" if the sender of the message cannot be authenticated. A malicious node may simply inject fake redirect messages in order to redirect traffic to a certain node.

IPv4 Fragmentation

- IPv4 packets that do not fit the outgoing link MTU will get fragmented into smaller packets that fit the link MTU.
 - The Identification field contains the same value for all fragments of an IPv4 packet.
 - The Fragment Offset field contains the relative position of a fragment of an IPv4 packet (counted in 64-bit words).

May 17, 2019 167 / 440

• The flag More Fragments (MF) is set if more fragments follow.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- The Don't Fragment (DF) flag can be set to indicate that a packet should not be fragmented.
- IPv4 allows fragments to be further fragmented without intermediate reassembly.

IPv4 allows routers on the path to fragment IPv4 packets. Reassembly of the fragments is done by the final receiver. This is inline with the general design idea that functionality that can be provided at the end points should be provided at the end points. Performing reassembly by the final receiver means that there is not fragmentation / reassembly state kept anywhere in the network.

Since IPv4 allows fragmentation on the path, it can happen that fragments get further fragmented. Here is a possible scenario:

A ----- R1 ----- R2 ----- R3 ----- B MTU 1500 MTU 1200 MTU 800 MTU 1500

If node A sends a 1500 octet IPv4 packet to B, it will be fragmented by R1 into a 1200 octet IPv4 packet and an 320 octet IPv4 fragment packet (assuming a standard IPv4 header with a size of 20 octets). The 1200 octet IPv4 packet will be further fragmented by R2 into a 800 octet IPv4 packet and a new 420 octet fragment. R3 will simply forward the received packets and fragments. Hence, node B will receive three packets (all with the same identification value): 800 octets (fragment-offset=0, MF=1), 420 octets (fragment-offset=800, MF=1), 320 octets (fragment-offset=1200, MF=0). Note that these packets may arrive in a different order and it is of course possible that some packets never arrive (hence an attempt to reassemble a packet must eventually time out).

Fragmentation Considered Harmful

Jürgen Schönwälder (Jacobs University Bremen)

- The receiver must buffer fragments until all fragments have been received. However, it is not useful to keep fragments in a buffer indefinitely. Hence, the TTL field of all buffered packets will be decremented once per second and fragments are dropped when the TTL field becomes zero.
- The loss of a fragment causes in most cases the sender to resend the original IP packet which in most cases gets fragmented as well. Hence, the probability of transmitting a large IP packet successfully goes quickly down if the loss rate of the network goes up.
- Since the Identification field identifies fragments that belong together and the number space is limited, one cannot fragment an arbitrary large number of packets.

In a classic paper [21], Christopher A. Kent and Jeffrey C. Mogul argued that fragmentation in the network can lead to poor performance since (i) it causes inefficient use of resources, (ii) lost fragments lead to degenerated performance, and (iii) efficient reassembly is difficult. This paper had a big impact and mechanisms were invented to discover the path MTU in order to avoid fragmentation within the network.

Computer Networks '2019

May 17, 2019 168 / 440

During the design of IPv6, a decision was made that links have to support a minimum MTU of 1280 octets and that IPv6 routers never fragment packets. The later, however, has serious consequences if ICMPv6 error messages are blocked or lost since routers that drop packets that are too big essentially become blackholes, causing higher layers to timeout.

MTU Path Discovery (RFC 1191)

Jürgen Schönwälder (Jacobs University Bremen)

- The sender sends IPv4 packets with the DF flag set.
- A router which has to fragment a packet with the DF flag turned on drops the packet and sends an ICMP message back to the sender which also includes the local maximum link MTU.
- Upon receiving the ICMP message, the sender adapts his estimate of the path MTU and retries.
- Since the path MTU can change dynamically (since the path can change), a once learned path MTU should be verified and adjusted periodically.
- Not all routers send necessarily the local link MTU. In this cases, the sender tries typical MTU values, which is usually faster than doing a binary search.

In IPv4 networks, path MTU discovery [29] is a mechanism that should be used to avoid fragmentation on the path. However, if path MTU discovery fails, IPv4 routers will still take care of things by fragmenting packets.

May 17, 2019 169 / 440

Computer Networks '2019

In IPv6 networks, path MTU discovery has to be used if the sender uses a link with an MTU larger than the minimum IPv6 link MTU of 1280 octets. If path MTU discovery fails in IPv6 networks, then large packets will simply disappear from the network, typically causing higher layers in the protocol stack to experience timeouts.

IPv4 over IEEE 802.3 (RFC 894)

Jürgen Schönwälder (Jacobs University Bremen)

- IPv4 packets are identified by the value 0x800 in the IEEE 802.3 type field.
- According to the maximum length of IEEE 802.3 frames, the maximum link MTU is 1500 byte.
- The mapping of IPv4 addresses to IEEE 802.3 addresses is table driven. Entries in so called mapping tables (sometimes also called address translation tables) can either be statically configured or dynamically learned.
- Note that the RFC 894 approach does not provide an assurance that the mapping is actually correct...

May 17, 2019 170 / 440

RFC 894 [18] defines how IPv4 packets are commonly encapsulated in Ethernet frames.

Jürgen Schönwälder (Jacobs University Bremen)

• The Address Resolution Protocol (ARP) resolved IPv4 addresses to link-layer addresses of neighboring nodes.

Computer Networks '2019

RFC 826 [32] defines how IPv4 addresses can be resolved to so called "hardware" addresses. RFC 903 [14] defines how a reverse resolution of a "hardware" address to an IPv4 address can be performed. In the common case, a "hardware address" is an Ethernet MAC address.

May 17, 2019 171 / 440

ARP and RARP

Jürgen Schönwälder (Jacobs University Bremen)

- The Hardware Type field identifies the address type used on the link-layer (the value 1 is used for IEEE 802.3 MAC addresses).
- The Protocol Type field identifies the network layer address type (the value 0x800 is used for IPv4).
- ARP/RARP packets use the 802.3 type value 0x806.
- The Operation field contains the message type: ARP Request (1), ARP Response (2), RARP Request (3), RARP Response (4).
- The sender fills, depending on the request type, either the Target IP Address field (ARP) or the Target Hardware Address field (RARP).

Computer Networks '2019

• The responding node swaps the Sender/Target fields and fills the empty fields with the requested information.

May 17, 2019 172 / 440

DHCP Version 4 (DHCPv4)

- The Dynamic Host Configuration Protocol (DHCP) allows nodes to retrieve configuration parameters from a central configuration server.
- A binding is a collection of configuration parameters, including at least an IP address, associated with or bound to a DHCP client.
- Bindings are managed by DHCP servers.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Bindings are typically valid only for a limited lifetime.
- See RFC 2131 for the details and the message formats.
- See RFC 3118 for security aspects due to lack of authentication.

DHCPv4 is widely used to supply hosts with IPv4 network configuration parameters (e.g., an IPv4 address, a default router address, a DNS server address). RFC 2131 [12] defines the DHCPv4 protocol and message formats while RFC 3118 [13] discusses security aspects of DHCPv4 while RFC 7819 [19] discusses privacy issues of DHCPv4.

May 17, 2019 173 / 440

DHCPv6 for IPv6 is defined in RFC 8415 [31]. Note that DHCPv6 is sufficiently different from DHCPv4 that integration between the two services has not been attempted yet (and it will likely never happen). There is ongoing debate where DHCPv6 should be used and whether IPv6 auto-configuration is not sufficient or even a better solution.

DHCPv4 Message Types

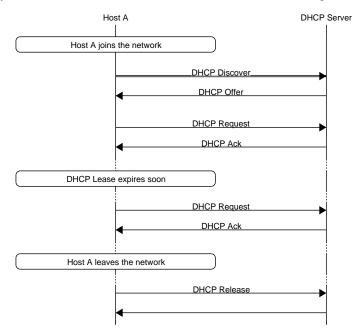

Jürgen Schönwälder (Jacobs University Bremen)

- The DHCPDISCOVER message is a broadcast message which is sent by DHCP clients to locate DHCP servers.
- The DHCPOFFER message is sent from a DHCP server to offer a client a set of configuration parameters.
- The DHCPREQUEST is sent from the client to a DHCP server as a response to a previous DHCPOFFER message, to verify a previously allocated binding or to extend the lease of a binding.
- The DHCPACK message is sent by a DHCP server with some additional parameters to the client as a positive acknowledgement to a DHCPREQUEST.
- The DHCPNAK message is sent by a DHCP server to indicate that the client's notion of a configuration binding is incorrect.

The following time sequence diagram shows a typical DHCPv4 exchange. Note that DHCP leases configuration parameters and hosts are expected to renew leases before they expire. Furthermore, it is appreciated by DHCP servers if hosts return their lease when leaving a network.

Computer Networks '2019

May 17, 2019 174 / 440

DHCPv4 Message Types (cont.)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- The DHCPDECLINE message is sent by a DHCP client to indicate that parameters are already in use.
- The DHCPRELEASE message is sent by a DHCP client to inform the DHCP server that configuration parameters are no longer used.
- The DHCPINFORM message is sent from the DHCP client to inform the DHCP server that only local configuration parameters are needed.

May 17, 2019 175 / 440

Part V Internet Routing

IP forwarding tables determine how traffic is moved through the Internet. For the global Internet to function, it is important that IP forwarding tables are setup "correctly" so that every node can reach any other node on the Internet. (We ignore for a moment situations where nodes are on purpose not globally reachable.) Of course, in a large scale network, everything is constantly changing since links and systems fail, business relationships change, or organizations simply decide to optimize traffic flows for different priorities. Hence, a global routing system should be (i) flexible, (ii) robust, and (iii) converge fast.

In the following, we will focus on routing for unicast communication. Multicast routing is a very different problem and the majority of wide-area traffic happens to be unicast traffic. We will look into the following three routing protocols since they use different techniques

- The *Routing Information Protocol* (RIP) is a simple *distance vector routing protocol*. It uses the distributed Bellman-Ford shortest path algorithm.
- The *Open Shortest Path First* (OSPF) routing protocol floods *link state* information so that every node can compute shortest paths using Dijkstra's shortest path algorithm. It is an example of a *link state routing protocol*.
- The *Border Gateway Protocol* (BGP) routing protocol propagates reachability information between Autonomous Systems. This information is used to make policy-based routing decisions.

The first two protocols (RIP and OSPF) were designed to distribute routing information within an Autonomous Systems. The BGP protocol is the standard protocol to exchange routing information between Autonomous Systems.

We will not cover the usage of BGP as an internal routing protocol of an Autonomous Systems and we will not cover other alternatives such as the *Intermediate System to Intermediate System* (IS-IS) routing protocol, another link state routing protocol adopted from the ISO/OSI protocol standards. We will also not cover routing protocols for special kinds of networks, e.g., the Routing Protocol for Low-Power and Lossy Networks (RPL), which is essentially establishing routing trees.

Section 21: Distance Vector Routing (RIP)

21 Distance Vector Routing (RIP)

Link State Routing (OSPF)

23 Path Vector Policy Routing (BGP)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 180 / 440

Bellman-Ford

Jürgen Schönwälder (Jacobs University Bremen)

- Let G = (V, E) be a graph with the vertices V and the edges E with n = |V| and m = |E|. Let D be an $n \times n$ distance matrix in which D(i, j) denotes the distance from node $i \in V$ to the node $j \in V$.
- Let H be an $n \times n$ matrix in which $H(i,j) \in E$ denotes the edge on which node $i \in V$ forwards a message to node $j \in V$.
- Let *M* be a vector with the link metrics, *S* a vector with the start node of the links and D a vector with the end nodes of the links.
- 1. Set $D(i,j) = \infty$ for $i \neq j$ and D(i,j) = 0 for i = j.
- 2. For all edges $l \in E$ and for all nodes $k \in V$: Set i = S[l] and j = D[l] and d = M[l] + D(j, k).
- 3. If d < D(i, k), set D(i, k) = d and H(i, k) = l.
- 4. Repeat from step 2 if at least one D(i, k) has changed. Otherwise, stop. Computer Networks '2019

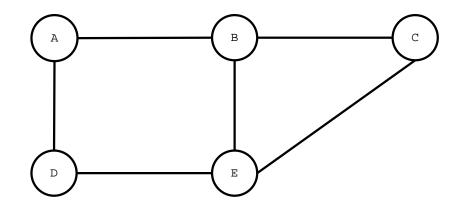

The Bellman-Ford algorithm computes shortest paths from a single source vertex to all of the other vertices in a weighted directed graph. It iteratively replaces approximations of the correct distance by better ones until the distances eventually reach the solution.

May 17, 2019 181 / 440

The algorithm initializes the distance to the source to 0 and all other nodes to infinity. Afterwards, for all edges, if the distance to the destination can be shortened by taking the edge, the distance is updated to the new lower value.

The Bellman-Ford algorithm can be distributed very easily. In the distributed version, vertices exchange their knowledge of the paths in rounds. This way, information about paths propagates until every vertex has learned all paths to all other vertices in the graph.

Bellman-Ford Example

	E	D-E	1		E	local	0				

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

Count-to-Infinity

• Consider the following topology:

A ---- B ---- C

- After some distance vector exchanges, C has learned that he can reach A by sending packets via B.
- When the link between A and B breaks, B will learn from C that he can still reach A at a higher cost (count of hops) by sending a packet to C.

May 17, 2019 183 / 440

- This information will now be propagated to C, C will update the hop count and subsequently announce a more expensive not existing route to B.
- This counting continues until the costs reach infinity.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

Split Horizon

- Idea: Nodes never announce the reachability of a network to neighbors from which they have learned that a network is reachable.
- Does not solve the count-to-infinity problem in all cases:

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- If the link between C and D breaks, B will not announce to C that it can reach D via C and A will not announce to C that it can reach D via C (split horizon).
- But after the next round of distance vector exchanges, A will announce to C that it can reach D via B and B will announce to C that it can reach D via A.

May 17, 2019 184 / 440

Split Horizon with Poisoned Reverse

- Idea: Nodes announce the unreachability of a network to neighbors from which they have learned that a network is reachable.
- Does not solve the count-to-infinity problem in all cases:

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- C now actively announces infinity for the destination D to A and B.
- However, since the exchange of the distance vectors is not synchronized to a global clock, the following exchange can happen:

May 17, 2019 185 / 440

Split Horizon with Poisoned Reverse

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- 1. C first announces infinity for the destination D to A and B.
- 2. A and B now update their local state with the metric infinity for the destination D directly via C. The other stale information to reach D via the other directly connected node is not updated.
- 3. A and B now send their distance vectors. A and B now learn that they can not reach D via the directly connected nodes. However, C learns that it can reach D via either A or B.
- 4. C now sends its distance vector which contains false information to A and B and the count-to-infinity process starts.

May 17, 2019 186 / 440

Routing Information Protocol (RIP)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- The Routing Information Protocol version 2 (RIP-2) defined in RFC 2453 is based on the Bellman-Ford algorithm.
- RIP defines infinity to be 16 hops. Hence, RIP can only be used in networks where the longest paths (the network diameter) is smaller than 16 hops.
- RIP-2 runs over the User Datagram Protocol (UDP) and uses the well-known port number 520.

May 17, 2019 187 / 440

- RIPng, defined in RFC 2080, adds support for IPv6 and uses UDP port 521.
- RIPng assumes that security is provided using IPv6 security mechanisms.

RIPng Message Format

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 189/440

RIPng Next Hop Route Table Entry

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Special RIPng route table entry to indicate a (different) next hop.
- Can be useful if RIPng is not run on all routers of a network.

May 17, 2019 190 / 440

Section 22: Link State Routing (OSPF)

- **2** Distance Vector Routing (RIP)
- Link State Routing (OSPF)
- **23** Path Vector Policy Routing (BGP)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 191/440

Dijkstra's Shortest Path Algorithm

- 1. All nodes are initially labeled with infinite costs (the costs are not yet known).
- 2. The cost of the root node is set to 0, the root node is marked as the current node.
- 3. The current node's cost label is marked permanent.

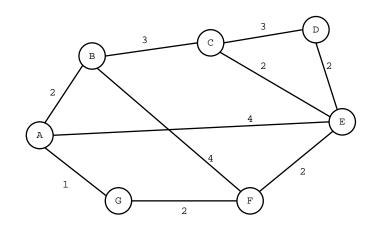

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- 4. For each node A adjacent to the current node C, the costs for reaching A are calculated as the costs of C plus the costs for the link from C to A. If the sum is less than A's cost label, the label is updated with the new cost and the name of the current node.
- 5. If there are still nodes with tentative cost labels, a node with the smallest costs is selected as the new current node. Goto step 3 if a new current node was selected.
- 6. The shortest paths to a destination node is given by following the labels from the destination node towards the root.

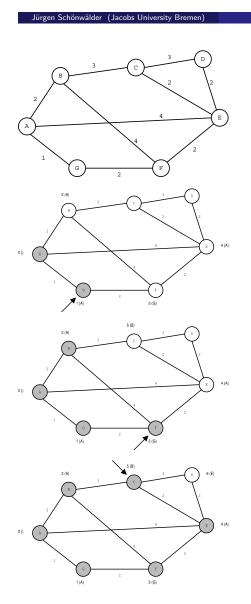

Dijkstra's algorithm computes shortest paths from a single source vertex to all of the other vertices in a weighted directed graph.

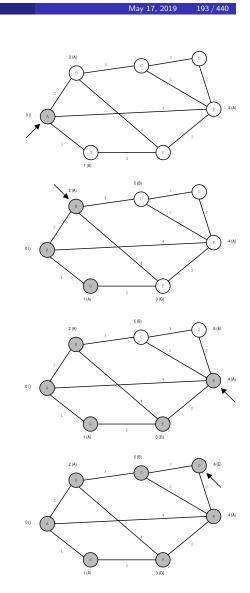

May 17, 2019 192 / 440

Dijkstra Example

Computer Networks '2019

Open Shortest Path First (OSPF)

Jürgen Schönwälder (Jacobs University Bremen)

- The Open Shortest Path First (OSPF) protocol defined in RFC 2328 is a link state routing protocol.
- OSPF version 3 is defined in RFC 5340 and supports IPv6.
- Every node independently computes the shortest paths to all the other nodes by using Dijkstra's shortest path algorithm.
- The link state information is distributed by flooding.
- OSPF introduces the concept of areas in order to control the flooding and computational processes.
- An OSPF area is a group of a set of networks within an autonomous system.
- The internal topology of an OSPF area is invisible for other OSPF areas. The routing within an area (intra-area routing) is constrained to that area.

The OSPF protocol [30, 6] is a widely used link-state routing protocol. There is a second widely used link-state routing protocol that is widely used on the Internet, called IS-IS (Intermediate System to Intermediate System). IS-IS originates from the ISO efforts to define network protocol standards.

Computer Networks '2019

May 17, 2019 194 / 440

OSPF Areas

- The OSPF areas are inter-connected via the OSPF backbone area (OSPF area 0). A path from a source node within one area to a destination node in another area has three segments (inter-area routing):
 - $1. \ \mbox{An intra-area path from the source to a so called area border router.}$
 - 2. A path in the backbone area from the area border of the source area to the area border router of the destination area.
 - 3. An intra-area path from the area border router of the destination area to the destination node.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 195 / 440

OSPF Router Classification

- OSPF routers are classified according to their location in the OSPF topology:
 - 1. Internal Router: A router where all interfaces belong to the same OSPF area.
 - 2. *Area Border Router*: A router which connects multiple OSPF areas. An area border router has to be able to run the basic OSPF algorithm for all areas it is connected to.
 - 3. *Backbone Router*: A router that has an interface to the backbone area. Every area border router is automatically a backbone router.
 - 4. AS Boundary Router: A router that exchanges routing information with routers belonging to other autonomous systems.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 196 / 440

OSPF Stub Areas

• *Stub Areas* are OSPF areas with a single area border router.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

• The routing in stub areas can be simplified by using default forwarding table entries, which significantly reduces the overhead.

- BGP-4 peers construct AS connectivity graphs to
 - detect and prune routing loops and

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- enforce policy decisions.
- BGP peers generally advertise only routes that should be seen from the outside (advertising policy).
- The final decision which set of announced paths is actually used remains a local policy decision.
- BGP-4 runs over a reliable transport (TCP) and uses the well-known port 179.

May 17, 2019 206 / 440

AS Categories (RFC 1772)

- Stub AS:
 - A Stub AS has only a single peering relationship to one other AS.
 - A Stub AS only carries local traffic.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Multihomed AS:
 - A Multihomed AS has peering relationships with more than one other AS, but refuses to carry transit traffic.
- Transit AS:
 - A Transit AS has peering relationships with more than one other AS, and is designed (under certain policy restrictions) to carry both transit and local traffic.

May 17, 2019 207 / 440

Routing Policies

• Policies are provided to BGP in the form of configuration information and determined by the AS administration.

Computer Networks '2019

• Examples:

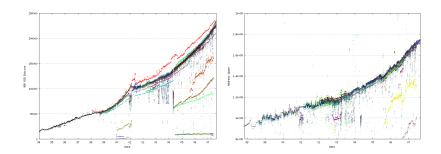

Jürgen Schönwälder (Jacobs University Bremen)

- 1. A multihomed AS can refuse to act as a transit AS for other AS's. (It does so by only advertising routes to destinations internal to the AS.)
- 2. A multihomed AS can become a transit AS for a subset of adjacent AS's, i.e., some, but not all, AS's can use the multihomed AS as a transit AS. (It does so by advertising its routing information to this set of AS's.)
- 3. An AS can favor or disfavor the use of certain AS's for carrying transit traffic from itself.

BGP-4 Phases and Messages

- Once the transport connection has been established, BGP-4 basically goes through three phases:
 - 1. The BGP4 peers exchange OPEN messages to open and confirm connection parameters
 - 2. The BGP4 peers exchange initially the entire BGP routing table. Incremental updates are sent as the routing tables change. Uses BGP UPDATE messages.
 - 3. The BGP4 peers exchange so called KEEPALIVE messages periodically to ensure that the connection and the BGP-4 peers are alive.
- Errors lead to a NOTIFICATION message and subsequent close of the transport connection.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 210 / 440

BGP-4 Open Message

Jürgen Schönwälder (Jacobs University Bremen)

- The Version field contains the protocol version number.
- The Autonomous System Number field contains the 16-bit AS number of the sender.
- The Hold Time field specifies the maximum time that the receiver should wait for a response from the sender.
- The BGP Identifier field contains a 32-bit value which uniquely identifies the sender.
- The Opt Parm Len field contains the total length of the Optional Parameters field or zero if no optional parameters are present.
- The Optional Parameters field contains a list of parameters. Each parameter is encoded using a tag-length-value (TLV) triple.

May 17, 2019 213 / 440

Computer Networks '2019

BGP-4 Update Message

+-	+
 +-	Unfeasible Routes Length (2 octets)
i	Withdrawn Routes (variable)
i	Total Path Attribute Length (2 octets)
1	Path Attributes (variable)
 +-	Network Layer Reachability Information (variable)

• The UPDATE message consists of two parts:

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- $1. \ \mbox{The list of unfeasible routes that are being withdrawn.}$
- 2. The feasible route to advertise.
- The Unfeasible Routes Length field indicates the total length of the Withdrawn Routes field in bytes.

May 17, 2019 214 / 440

BGP-4 Update Message

Jürgen Schönwälder (Jacobs University Bremen)

- The Withdrawn Routes field contains a list of IPv4 address prefixes that are being withdrawn from service.
- The Total Path Attribute Length field indicates the total length of the Path Attributes field in bytes.
- The Path Attributes field contains a list of path attributes conveying information such as

Computer Networks '2019

- the origin of the path information,
- the sequence of AS path segments,
- the IPv4 address of the next hop border router, or
- the local preference assigned by a BGP4 speaker.
- The Network Layer Reachability Information field contains a list of IPv4 prefixes that are reachable via the path described in the path attributes fields.

May 17, 2019 215 / 440

BGP-4 Notification Message

0	1	2	3				
0 1 2 3 4 5 6 7 8 9	0 1 2 3 4 5 6 7	8901234567	8901

Error code Error subcode Data							
+-	+-+-+-+-+-+		+				
I I							
+-							

- NOTIFICATION messages are used to report errors.
- The transport connection is closed immediately after sending a NOTIFICATION.
- Six error codes plus 20 sub-codes.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 216 / 440

BGP-4 Keep Alive Message

- BGP-4 peers periodically exchange KEEPALIVE messages.
- A KEEPALIVE message consists of the standard BGP-4 header with no additional data.
- KEEPALIVE messages are needed to verify that shared state information is still present.
- If a BGP-4 peer does not receive a message within the Hold Time, then the peer will assume that there is a communication problem and tear down the connection.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 217/440

BGP Communities

- BGP communities are 32 bit values used to convey user-defined information
- A community is a group of destinations which share some common property
- Some well-known communities, e.g.:
 - NO_EXPORT
 - NO_ADVERTISE
- Most take the form AS:nn (written as 701:120) where the meaning of nn (encoded in the last 16 bits) depends on the source AS (encoded in the first 16 bits)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 218 / 440

• Mostly used for special treatment of routes

Internal BGP (iBGP)

- Use of BGP to distribute routing information within an AS.
- Requires to setup BGP sessions between all routers within an AS.
- Route Reflectors can be used to reduce the number of internal BGP sessions:
 - The Route Reflector collets all routing information and distributes it to all internal BGP routers.
 - Scales with O(n) instead of $O(n^2)$ internal BGP sessions.
- BGP Confederations are in essence internal sub-ASes that do full mesh iBGP with a few BGP sessions interconnecting the sub-ASes.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 219 / 440

BGP Route Selection (cbgp)

- 1. Ignore if next-hop is unreachable
- 2. Prefer locally originated networks
- 3. Prefer highest Local-Pref
- 4. Prefer shortest AS-Path
- 5. Prefer lowest Origin
- 6. Prefer lowest Multi Exit Discriminator (metric)
- 7. Prefer eBGP over iBGP
- 8. Prefer nearest next-hop
- 9. Prefer lowest Router-ID or Originator-ID

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- 10. Prefer shortest Cluster-ID-List
- 11. Prefer lowest neighbor address

One of the route selection criteria is the AS path length. Given that that AS path length is ranked relatively high, it is often used to artificially increase the AS path length (by listing some ASes multiple times) in order to make an announced path less attractive.

May 17, 2019 220 / 440

BGP's and Count-to-Infinity

- BGP does not suffer from the count-to-infinity problem of distance vector protocols:
 - The AS path information allows to detect loops.
- However, BGP iteratively explores longer and longer (loop free) paths.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 221/440

Multiprotocol BGP

- Extension to BGP-4 that makes it possible to distribute routing information for additional address families
- Announced as a capability in the open message
- Information for new protocol put into new path attributes
- Used to support IPv6, multicast, VPNs, ...

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 222 / 440

Part VI Internet Transport Layer (UDP, TCP)

The transport layer provides communication services for applications running on hosts. The transport layer is responsible for delivering data to the appropriate application process on the host computers and hence it has a multiplexing and demultiplexing function. The transport layer often is also in charge to segment data received from applications into suitable packets. The services provided by the transport layer to applications can differ since applications may have very different requirements. A file transfer application likely prefers a transport that guarantees that data is delivered in sequence and without any gaps. On the other hand, an online gaming application may prefer timeliness of data over completeness and may tolerate data arriving out of order.

Traditionally, transport layer protocols have been implemented in operating system kernels with applications protocols residing in user space. Hence, the services of the transport layer tend to match the communication specific interface abstraction between user space and kernel space (such as the socket API).

Section 24: Transport Layer Overview

24 Transport Layer Overview

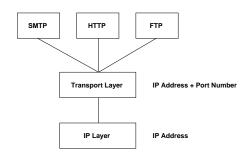

25 User Datagram Protocol (UDP)

26 Transmission Control Protocol (TCP)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 225 / 440

Internet Transport Layer

Jürgen Schönwälder (Jacobs University Bremen)

- Network layer addresses identify interfaces on nodes (node-to-node significance).
- Transport layer addresses identify communicating application processes (end-to-end significance).
- 16-bit port numbers enable the multiplexing and demultiplexing of packets at the transport layer.

Computer Networks '2019

May 17, 2019 226 / 440

In a properly layered architecture, protocol layers would have independent addresses and there would be a flexible mapping function mapping the addresses used by the different layers. The Internet design is not a properly layered architecture since network layer addresses are simply extended to provide transport layer addresses. While this design makes simplifies the mapping function between the layers, it has a significant drawback: Changing the network layer endpoint causes all transport layer endpoints to become invalid.

This is a significant drawback for mobile systems that can easily move between networks. When a node moves from one network to another, the node has to obtain a new IP address, which is topologically consistent with the new network (i.e., uses the prefix of the new network). This means the old address, that was topologically consistent with the old network (i.e., used the prefix of the old network), becomes unusable. A lot of work has been spent to address this problem, for example by dynamically establishing tunnels that allow a system to continue to use the old now invalid address or by creating a new slim layer that provides a proper separation of transport layer address from network layer addresses. So far, none of the solutions gained wide deployment. Instead, applications learned how to deal gracefully with errors and interruptions caused by changes of a nodes network attachment.

Internet Transport Layer Protocols Overview

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- The User Datagram Protocol (UDP) provides a simple unreliable best-effort datagram service.
- The *Transmission Control Protocol* (TCP) provides a bidirectional, connection-oriented and reliable data stream.
- The *Stream Control Transmission Protocol* (SCTP) provides a reliable transport service supporting sequenced delivery of messages within multiple streams, maintaining application protocol message boundaries (application protocol framing).
- The *Datagram Congestion Control Protocol* (DCCP) provides a congestion controlled, unreliable flow of datagrams suitable for use by applications such as streaming media.

The UDP protocol is defined in RFC 768 [33] and the TCP protocol is defined in RFC 793 [36]. Both documents appeared in the early 1980s. While the core of the specifications are still used today, there have been a number of updates and extensions on certain aspects, in particular related to congestion control.

May 17, 2019 227 / 440

The SCTP protocol first appeared as RFC 2960 [41] in 2000 and a major revision was published as RFC 4960 [40] in 2007. SCTP provides multiple independent streams within an association and it can provide different types of services.

The DCCP protocol first appeared in RFC 4340 [24]. There is a nice paper describing the design decisions that led to DCCP [25].

Unfortunately, both SCTP and DCCP have failed so far to gain wide-spread adoption. One key factor is a chicked-or-egg problem: Unless SCTP and DCCP are available everywhere (means all relevant operating system kernels but also middleboxes), there won't be applications using it. Without applications using SCTP and DCCP, they will not be implemented everywhere.

Google started a new effort to create new transport protocol called QUIC [3], which aims to minimize latency while at the same time mandating security. In order to avoid the chicked-or-egg problem, they designed QUIC (a transport protocol) over UDP (another transport protocol). This somewhat surprising design (from an architectural point of view) has the benefit that a QUIC implementation can be conveniently be shipped with applications. This of courses raises questions to what extend networking protocols should be implemented in kernel space at all and how we deal with applications that all come with their own networking stacks.

From an academic perspective, it is highly relevant to study the different protocol designs. From a practical perspective, most traffic today is running over TCP. This may be changed by QUIC eventually but as of today, it is unlikely that SCTP or DCCP will play a significant role at the transport layer. But it is important that this is not due to significant technical deficiencies but to the economic system around the Internet [5, 17].

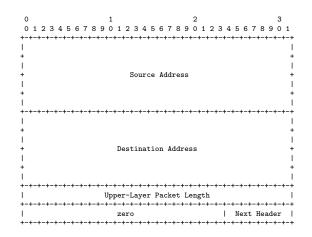

IPv4 Pseudo Header

0	1	2	3
0 1 2 3 4 5 6	789012345	678901234567	8901
+-+-+-+-+-+-+-+	+-+-+-+-+-+-+-+-+-	+-	+-+-+-+

Section 25: User Datagram Protocol (UDP)

24 Transport Layer Overview

26 Transmission Control Protocol (TCP)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 230 / 440

User Datagram Protocol (UDP)

Jürgen Schönwälder (Jacobs University Bremen)

- UDP (RFC 768) provides an unreliable datagram transport service.
- The UDP header simply extends the IP header with source and destination port numbers and a checksum.
- UDP adds multiplexing services to the best effort packet delivery services provided by the IP layer.
- UDP datagrams can be multicasted to a group of receivers.

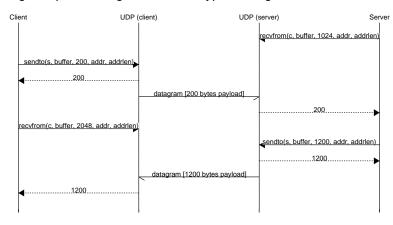

The User Datagram Protocol (UDP) is defined in RFC 768 [33]. The UDP datagram header fields have the following meaning:

Computer Networks '2019

May 17, 2019 231 / 440

- The Source Port field contains the port number used by the sending application layer process.
- The Destination Port field contains the port number used by the receiving application layer process.
- The Length field contains the length of the UDP datagram including the UDP header counted in bytes.
- The Checksum field contains the Internet checksum computed over the pseudo header, the UDP header and the payload contained in the UDP packet.

The following message sequence diagram shows a typical usage of UDP:

Section 26: Transmission Control Protocol (TCP)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 232/440

24 Transport Layer Overview

• TCP (RFC 793) provides a bidirectional connection-oriented and reliable data stream over an unreliable connection-less network protocol.

The Transmission Control Protocol	(TCP) is defined in RFC 793 [36].	The TCP segment header fields
have the following meaning:		

May 17, 2019 233 / 440

- The Source Port field contains the port number used by the sending application layer process.
- The Destination Port field contains the port number used by the receiving application layer process.
- The Sequence Number field contains the sequence number of the first data byte in the segment. During connection establishment, this field is used to establish the initial sequence number.
- The Acknowledgment Number field contains the next sequence number which the sender of the acknowledgement expects.
- The Offset field contains the length of the TCP header including any options, counted in 32-bit words.
- The Window field indicates the number of data bytes which the sender of the segment is willing to receive (the window starts with the acknowledgement number and this field indicates the size of the window).
- The Checksum field contains the Internet checksum computed over the pseudo header, the TCP header and the data contained in the TCP segment.
- The Urgent Pointer field points, relative to the actual segment number, to important data if the URG flag is set.
- The Options field can contain additional options.

Transmission Control Protocol (TCP)

FlagDescriptionURGIndicates that the Urgent Pointer field is significantACKIndicates that the Acknowledgment Number field is significantPSHData should be pushed to the application as quickly as possibleRSTReset of the connectionSYNSynchronization of sequence numbersFINNo more data from the sender

• The Flags field contains a set of binary flags.

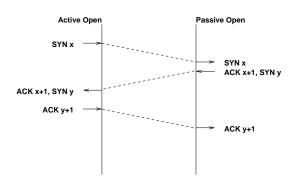

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

• The flags control how other header fields are interpreted.

May 17, 2019 234 / 440

TCP Connection Establishment

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

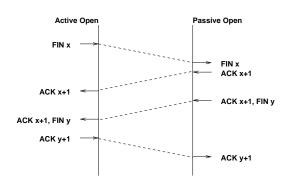

• Handshake protocol establishes TCP connection parameters and announces options.

May 17, 2019 235 / 440

• Guarantees correct connection establishment, even if TCP packets are lost or duplicated.

TCP Connection Tear-down

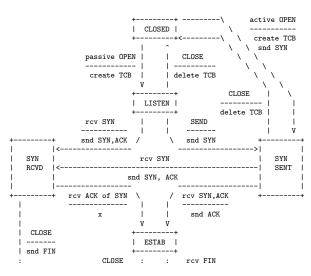

• TCP provides initially a bidirectional data stream.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

• A TCP connection is terminated when both unidirectional connections have been closed. (It is possible to close only one half of a connection.)

 239 / 440

231

TCP Flow Control Optimizations

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Nagle's Algorithm
 - When data comes into the sender one byte at a time, just send the first byte and buffer all the rest until the byte in flight has been acknowledgement.
 - This algorithm provides noticeable improvements especially for interactive traffic where a quickly typing user is connected over a rather slow network.
- Clark's Algorithm
 - The receiver should not send a window update until it can handle the maximum segment size it advertised when the connection was established or until its buffer is half empty.
 - Prevents the receiver from sending a very small window updates (such as a single byte).

May 17, 2019 240 / 440

TCP Congestion Control

Jürgen Schönwälder (Jacobs University Bremen)

- TCP's congestion control introduces the concept of a congestion window (*cwnd*) which defines how much data can be in transit.
- The congestion window is maintained by a TCP sender in addition to the flow control receiver window (*rwnd*), which is advertised by the receiver.
- The sender uses these two windows to limit the data that is sent to the network and not yet received (*flightsize*) to the minimum of the receiver and the congestion window:

$flightsize \leq min(cwin, rwin)$

• The key problem to be solved is the dynamic estimation of the congestion window.

Congestion control is of fundamental importance to avoid a collapse of the Internet. Many RFCs have been written on topics related to congestion control. RFC 5783 [42] provides an overview (as of Spring 2010). RFC 5681 [1] discusses the details of TCP congestion control.

Computer Networks '2019

May 17, 2019 241 / 440

TCP Congestion Control (cont.)

Jürgen Schönwälder (Jacobs University Bremen)

• The initial window (IW) is usually initialized using the following formula:

 $IW = min(4 \cdot SMSS, max(2 \cdot SMSS, 4380bytes))$

SMSS is the sender maximum segment size, the size of the largest sement that the sender can transmit (excluding TCP/IP headers and options).

- During slow start, the congestion window *cwnd* increases by at most *SMSS* bytes for every received acknowledgement that acknowledges data. Slow start ends when *cwnd* exceeds *ssthresh* or when congestion is observed.
- Note that this algorithm leads to an exponential increase if there are multiple segments acknowledged in the *cwnd*.

Computer Networks '2019

May 17, 2019 242 / 440

TCP Congestion Control (cont.)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

• During congestion avoidance, *cwnd* is incremented by one full-sized segment per round-trip time (RTT). Congestion avoidance continues until congestion is detected. One formula commonly used to update *cwnd* during congestion avoidance is given by the following equation:

cwnd = *cwnd* + (*SMSS* * *SMSS*/*cwnd*)

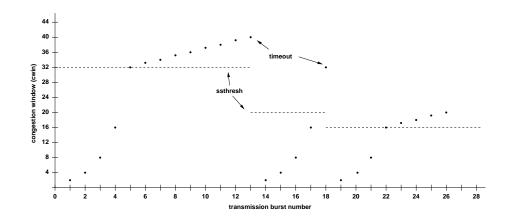

This adjustment is executed on every incoming non-duplicate ACK.

• When congestion is noticed (the retransmission timer expires), then *cwndv* is reset to one full-sized segment and the slow start threshold *ssthresh* is updated as follows:

$$ssthresh = max(flightsize/2, 2 \cdot SMSS)$$

May 17, 2019 243 / 440

TCP Congestion Control (cont.)

Computer Networks '2019

May 17, 2019 244 / 440

• Congestion control with an initial window size of 2K.

Jürgen Schönwälder (Jacobs University Bremen)

236

Retransmission Timer

- The retransmission timer controls when a segment is resend if no acknowledgement has been received.
- The retransmission timer *RTT* needs to adapt to round-trip time changes.
- General idea:
 - Measure the current round-trip time
 - Measure the variation of the round-trip time
 - Use the estimated round-trip time plus the measured variation to calculate the retransmit timeout
 - Do not update the estimators if a segment needs to be retransmitted (Karn's algorithm).

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 245/440

Retransmission Timer

• If an acknowledgement is received for a segment before the associated retransmission timer expires:

$$RTT = \alpha \cdot RTT + (1 - \alpha)M$$

M is the measured round-trip time; α is typicall $\frac{7}{8}$.

• The standard deviation is estimated using:

$$D = \alpha \cdot D + (1 - \alpha)|RTT - M|$$

 $\boldsymbol{\alpha}$ is a smoothing factor.

• The retransmission timeout *RTO* is determined as follows:

$$RTO = RTT + 4 \cdot D$$

 The factor 4 has been choosen empirically.

 Jürgen Schönwälder (Jacobs University Bremen)
 Computer Networks '2019

May 17, 2019 246 / 440

Fast Retransmit / Fast Recovery

- TCP receivers should send an immediate duplicate acknowledgement when an out-of-order segment arrives.
- The arrival of four identical acknowledgements without the arrival of any other intervening packets is an indication that a segment has been lost.
- The sender performs a fast retransmission of what appears to be the missing segment, without waiting for the retransmission timer to expire.
- Upon a fast retransmission, the sender does not exercise the normal congestion reaction with a full slow start since acknowledgements are still flowing.
- See RFC 2581 section 3.1 for details.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 247 / 440

Karn's Algorithm

- The dynamic estimation of the *RTT* has a problem if a timeout occurs and the segment is retransmitted.
- A subsequent acknowledgement might acknowledge the receipt of the first packet which contained that segment or any of the retransmissions.
- Karn suggested that the *RTT* estimation is not updated for any segments which were retransmitted and that the *RTO* is doubled on each failure until the segment gets through.
- The doubling of the *RTO* leads to an exponential back-off for each consecutive attempt.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 248 / 440

Selected TCP Options

- Maximum Segment Size (MSS):
 - Communicates the maximum receive segment size of the sender of this option during connection establishment
- Window Scale (WS):
 - The number carried in the 16-bit Window field of a TCP header is scaled (shifted) by a certain constant to enable windows larger than 2¹⁶ octets
- TimeStamps (TS):
 - Timestamps exchanged in every TCP header to deal with the 32-bit sequence number space limitation (and to enhance round-trip time measurements)
- Selective Acknowledgment (SACK):

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

• Indicate which blocks of the sequence number space are missing and which blocks are not (to improve cummulative acknowledgements)

May 17, 2019 249 / 440

Explicit Congestion Notification

Jürgen Schönwälder (Jacobs University Bremen)

- Idea: Routers signal congestion by setting some special bits in the IP header.
- The ECN bits are located in the Type-of-Service field of an IPv4 packet or the Traffic-Class field of an IPv6 packet.
- TCP sets the ECN-Echo flag in the TCP header to indicate that a TCP endpoint has received an ECN marked packet.
- TCP sets the Congestion-Window-Reduced (CWR) flag in the TCP header to acknowledge the receipt of and reaction to the ECN-Echo flag.
- \implies ECN uses the ECT and CE flags in the IP header for signaling between routers and connection endpoints, and uses the ECN-Echo and CWR flags in the TCP header for TCP-endpoint to TCP-endpoint signaling.

Computer Networks '2019

May 17, 2019 250 / 440

Explicit Congestion Notification (ECN) was introduced in RFC 3168 [38].

TCP Performance

Jürgen Schönwälder (Jacobs University Bremen)

- Goal: Simple analytic model for steady state TCP behavior.
- We only consider congestion avoidance (no slow start).
- W(t) denotes the congestion window size at time t.
- In steady state, W(t) increases to a maximum value W where it experiences congestion. As a reaction, the sender sets the congestion window to ¹/₂W.

Computer Networks '2019

- The time interval needed to go from $\frac{1}{2}W$ to W is T and we can send a window size of packets every RTT.
- Hence, the number *N* of packets is:

$$N = \frac{1}{2} \frac{T}{RTT} \left(\frac{W}{2} + W \right)$$

May 17, 2019 251 / 440

TCP Performance (cont.)

- The time T between two packet losses equals $T = RTT \cdot W/2$ since the window increases linearly.
- By substituting T and equating the total number of packets transferred with the packet loss probability, we get

$$\frac{W}{4} \cdot \left(\frac{W}{2} + W\right) = \frac{1}{p} \Longleftrightarrow W = \sqrt{\frac{8}{3p}}$$

where p is the packet loss probability (thus $\frac{1}{p}$ packets are transmitted between each packet loss).

• The average sending rate $\bar{X}(p)$, that is the number of packets transmitted during each period, then becomes:

Computer Networks '2019

$$\bar{X}(p) = rac{1/p}{RTT \cdot W/2} = rac{1}{RTT} \sqrt{rac{3}{2p}}$$

May 17, 2019 252 / 440

Example:

• RTT = 200ms, p = 0.05

Jürgen Schönwälder (Jacobs University Bremen)

- $\bar{X}(p) \approx 27.4 pps$
- With 1500 byte segments, the data rate becomes $\approx 32Kbps$

Given this formula, it becomes clear that high data rates (say 10Gbps or 1 Tbps) require an extremely and unrealistic small packet error rate. TCP extensions to address this problem can be found in RFC 3649 [15].

Part VII Middleboxes, Firewalls, Network Address Translators

In a simple (and perhaps idealistic) world, there would only be hosts and routers implementing the network layer protocols and the transport layer protocols would only be implemented at the end devices, i.e., the hosts. Unfortunately, there are a number of technical and business reasons to introduce additional network functions that implement network and transport layer functionality in the network in order to change or 'enhance' the network behavior. These are commonly referred to as middleboxes, although a newer terminology is developing where people talk about network functions.

Two classic types of middleboxes are firewalls and network address translators. Firewalls implement a network security function and they monitor and control incoming and outgoing network traffic based on predetermined security rules. The security rules are primarily used to protect a network from the outside but it is often equally important to also protect the outside from a potentially misbehaving network. Network firewalls filter traffic between two or more networks and run on network hardware. Host-based firewalls run on host computers and control network traffic in and out of those machines.

Network address translators are translating IP addresses or IP addresses and port numbers to other IP addresses or IP addresses and port numbers. Network address translation is widely deployed on IPv4 networks due to the limited size of the global IPv4 address space. Since IPv6 has a much larger address space, network address translators should not be needed in IPv6 networks. However, in networks providing only IPv6 service, network address translation can be tool to achieve connectivity to (legacy) hosts that are only reachable via IPv4.

Section 27: Middleboxes

27 Middleboxes

28 Firewalls

29 Network Address Translators

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 254/440

Middleboxes

Definition (RFC 3234)

Jürgen Schönwälder (Jacobs University Bremen)

A middlebox is any intermediary device performing functions other than the normal, standard functions of an IP router on the datagram path between a source host and destination host.

• A middlebox is not necessarily a physical box — it is usually just a function implemented in some other box.

Computer Networks '2019

- Middleboxes challenge the End-to-End principle and the hourglass model of the Internet architecture.
- Middleboxes are popular (whether we like this or not).

In the early days, middleboxes were often implemented and sold as physical boxes - hence the name middlebox [4]. Since installing and maintaining many different boxes, all with separate power supplies, in distributed networks is expensive, there is currently a movement to virtualize middlebox functions. This is known under the term network function virtualization. The general idea is to deploy small clouds within the network and to implement middlebox functionality in virtualized computing systems. A big challenge is to determine through which collection of virtual network functions traffic has to pass and to implement virtual network functions efficiently to support datarates provided by modern link-layer technologies.

May 17, 2019 255 / 440

Concerns about Middleboxes

- Protocols designed without consideration of middleboxes may fail, predictably or unpredictably, in the presence of middleboxes.
- Middleboxes introduce new failure modes; rerouting of IP packets around crashed routers is no longer the only case to consider.
- Configuration is no longer limited to the two ends of a session; middleboxes may also require configuration and management.

May 17, 2019 256 / 440

• Diagnosis of failures and misconfigurations is more complex.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

Types of Middleboxes

- *Network Address Translators (NAT)*: A function that dynamically assigns a globally unique address to a host that doesn't have one, without that host's knowledge.
- *NAT with Protocol Translator (NAT-PT)*: A function that performs NAT between an IPv6 host and an IPv4 network, additionally translating the entire IP header between IPv6 and IPv4 formats.
- *IP Tunnel Endpoints*: Tunnel endpoints, including virtual private network endpoints, use basic IP services to set up tunnels with their peer tunnel endpoints which might be anywhere in the Internet.

May 17, 2019 257 / 440

• *Transport Relays*: A middlebox which translates between two transport layer instances.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

Types of Middleboxes (cont.)

Jürgen Schönwälder (Jacobs University Bremen)

- *Packet classifiers, markers and schedulers*: Packet classifiers classify packets flowing through them according to policy and either select them for special treatment or mark them, in particular for differentiated services.
- *TCP performance enhancing proxies*: "TCP spoofer" are middleboxes that modify the timing or action of the TCP protocol in flight for the purposes of enhancing performance.
- Load balancers that divert/munge packets: Techniques that divert packets from their intended IP destination, or make that destination ambiguous.
- *IP Firewalls*: A function that screens and rejects packets based purely on fields in the IP and Transport headers.
- Application Firewalls: Application-level firewalls act as a protocol end point and relay

Computer Networks '2019

May 17, 2019 258 / 440

Types of Middleboxes (cont.)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Application-level gateways (ALGs): ALGs translate IP addresses in application layer protocols and typically complement IP firewalls.
- *Transcoders*: Functions performing some type of on-the-fly conversion of application level data.
- *Proxies*: An intermediary program which acts as both a server and a client for the purpose of making requests on behalf of other clients.
- Caches: Caches are functions typically intended to optimise response times.
- *Anonymisers*: Functions that hide the IP address of the data sender or receiver. Although the implementation may be distinct, this is in practice very similar to a NAT plus ALG.

Section 28: Firewalls

27 Middleboxes

29 Network Address Translators

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 260 / 440

Firewalls

- A firewall is a system (or a set of systems) that enforce access control policies between two (or more) networks.
- Conservative firewalls allow known desired traffic and reject everything else.
- Optimistic firewalls reject known unwanted traffic and allow the rest.
- Firewalls typically consist of packet filters, transport gateways and application level gateways.
- Firewalls not only protect the "inside" from the "outside", but also the "outside" from the "inside".

May 17, 2019 261 / 440

 $\Rightarrow\,$ There are many ways to circumvent firewalls if internal and external hosts cooperate.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

Firewall Architectures

- The simplest architecture is a packet filter which is typically implemented within a router that connects the internal network with the external network.
- Sometimes called a "screening router".

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 262 / 440

Firewall Architectures

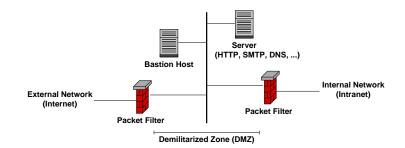

External Network (Internet)		Internal Network (Intranet)
	Bastion Host	

- A bastion host is a multihomed host connected to the internal and external network which does not forward IP datagrams but instead provides suitable gateways.
- Effectively prevents any direct communication between hosts on the internal network with hosts on the external network.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 263/440

Firewall Architectures

Jürgen Schönwälder (Jacobs University Bremen)

• The most common architecture consists of two packet filters which create a demilitarized zone (DMZ).

Computer Networks '2019

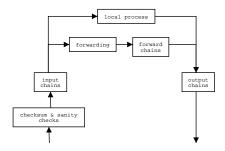

May 17, 2019 264 / 440

• Externally visible servers and gateways are located in the DMZ.

256

Packetfilter Example: Linux ipchains

Jürgen Schönwälder (Jacobs University Bremen)

- Input chains are lists of filter rules applied to all incoming IP packets.
- Output chains are lists of filter rules applied to all outgoing IP packet.
- Forward chains are lists of fiter rules applied to all forwarded IP packets.

There is currently a movement to reimplement the traditional firewall code using extended Berkeley Packet Filters (eBPF). The eBPF approach uses a programmable in-kernel virtual machine to manipulate the packet handlink in the kernel.

Computer Networks '2019

May 17, 2019 265 / 440

Section 29: Network Address Translators

27 Middleboxes

28 Firewalls

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 266 / 440

Network Address Translators

• Basic Network Address Translation (NAT): Translates private IP addresses into public IP addresses.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Network Address Port Translation (NAPT): Translates transport endpoint identifiers. NAPT allows to share a single public address among many private addresses (masquerading).
- Bi-directional NAT (Two-Way NAT): Translates outbound and inbound and uses DNS-ALGs to facilitate bi-directional name to address mappings.
- *Twice NAT*:

A variation of a NAT which modifies both the source and destination addresses of a datagram. Used to join overlapping address domains.

May 17, 2019 267 / 440

Full Cone NAT

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- A full cone NAT is a NAT where all requests from the same internal IP address and port are mapped to the same external IP address and port.
- Any external host can send a packet to the internal host, by sending a packet to the mapped external address.

May 17, 2019 269 / 440

Restricted Cone NAT

- A restricted cone NAT is a NAT where all requests from the same internal IP address and port are mapped to the same external IP address and port.
- Unlike a full cone NAT, an external host (with IP address X) can send a packet to the internal host only if the internal host had previously sent a packet to IP address X.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 270 / 440

Port Restricted Cone NAT

- A port restricted cone NAT is like a restricted cone NAT, but the restriction includes port numbers.
- Specifically, an external host can send a packet, with source IP address X and source port P, to the internal host only if the internal host had previously sent a packet to IP address X and port P.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 271/440

Symmetric NAT

- A symmetric NAT is a NAT where all requests from the same internal IP address and port, to a specific destination IP address and port, are mapped to the same external IP address and port.
- If the same host sends a packet with the same source address and port, but to a different destination, a different mapping is used.
- Only the external host that receives a packet can send a UDP packet back to the internal host.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 272 / 440

STUN NAT Traversal (RFC 5389)

- Session Traversal Utilities for NAT (STUN)
- Client / server protocol used for NAT discovery:
 - 1. The client sends a request to a STUN server
 - 2. The server returns a response containing the IP address seen by the server (i.e., a mapped address)
 - 3. The client compares its IP address with the IP address returned by the server; if they are different, the client is behind a NAT and learns its mapped address
- RFC 5780 details a number of tests that can be performed using STUN to determine the behaviour of a NAT.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 273/440

Part VIII Domain Name System (DNS)

Application protocols primarily use names to refer to systems providing application specific services. A common service naming scheme are universal resource identifiers, which are build on the notion of names, or more specifically domain names. The term "domain name" indicates that a certain authority has control over the names in their "domain".

The Domain Name System (DNS) provides a name resolution service. It was defined in the 1980s when manual maintenance of names had to be replaced by a more scalable solution.

Domain names can be though of as (components of) application layer addresses and the DNS protocol provides the mapping of these addresses to lower layers. The mapping as it was defined originally is kind of violating layering since application layer names are commonly resolved to network layer addresses and not to transport layer addresses.

Section 30: Overview and Features

30 Overview and Features

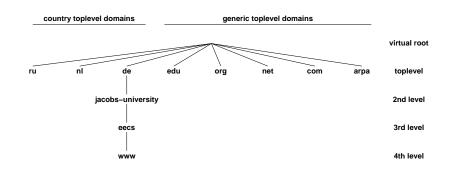

- **31** Resource Records
- **32** Message Formats
- **Security and Dynamic Updates**
- 34 Creative Usage

266

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 276/440

Domain Name System (DNS)

Jürgen Schönwälder (Jacobs University Bremen)

- The Domain Name System (DNS) provides a global infrastructure to map human friendly domain names into addresses (and other data).
- The DNS is a critical resource since most Internet users depend on name resolution services provided by the DNS.

May 17, 2019 277 / 440

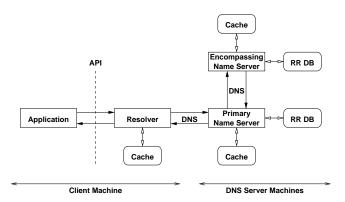

The core of the domain name system is defined in RFC 1034 [27] and RFC 1035 [28]. Paul Mockapetris has received several awards for the definition of the domain name system.

Computer Networks '2019

While we often write google.com, what we really mean is google.com. since the trailing dot refers to the root of the DNS namespace.

Resolver and Name Resolution

Jürgen Schönwälder (Jacobs University Bremen)

• The resolver is typically tightly integrated into the operating system (or more precisely standard libraries).

Computer Networks '2019

May 17, 2019 278 / 440

The common high-level C library API for name resolution consists of the functions getaddrinfo() and getnameinfo(). To access the resolver directly, it is necessary to use resolver specific functions. The BIND resolver API is commonly available on Unix systems. There are also several alternative resolver library implementations that provide asynchronous (non-blocking) APIs. Hence, some applications may not use the system's resolver library but their own implementations.

The DNS has been designed to scale by supporting caching well. Data obtained from the DNS can be cached in several places in order to reduce the amount of DNS queries.

Most hosts on the Internet do not resolve names themself but instead the resolver is sending recursive queries to a domain name resolver (often part of the local network). The (local) domain name resolver, upon receipt of a recursive query, sends multiple queries to walk the tree from the root down to the domain name server that has an authoritative answer. Multiple users using a common domain name resolver provides caching advantages and a common domain name resolver may also hide where specific name resolution requests are originating from. On the other hand, the domain name resolver does get to see all domain name resolution requests, which can reveal quite a bit of sensitive information. (Web browsers tend to start the resolution of all embedded links as soon as a page is renders and hence pages can have certain name resolution signatures.)

Hosts typically learn the address of a domain name resolver when they configure an interface, i.e., via auto-configuration or DHCP. There are also publically known domain name resolvers:

- Google is operating 8.8.8.8 and 8.8.4.4 and 2001:4860:4860::8888 and 2001:4860:4860::8844.
- Cloudflare is operating 1.1.1.1 and 1.0.0.1 and 2606:4700:4700::1111. (Cloudflare claims that they do not collect and sell data.)

DNS Characteristics

• Hierarchical name space with a virtual root.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Administration of the name space can be delegated along the path starting from the virtual root.
- A DNS server knows a part (a zone) of the global name space and its position within the global name space.
- Name resolution queries can in principle be sent to arbitrary DNS servers. However, it is good practice to use a local DNS server as the primary DNS server.
- Recursive queries cause the queried DNS server to contact other DNS servers as needed in order to obtain a response to the query.
- The original DNS protocol does not provide sufficient security. There is usually no reason to trust DNS responses.

May 17, 2019 279 / 440

DNS Labels and Names

- The names (labels) on a certain level of the tree must be unique and may not exceed 63 byte in length. The character set for the labels is historically 7-bit ASCII. Comparisons are done in a case-insensitive manner.
- Labels must begin with a letter and end with a letter or decimal digit. The characters between the first and last character must be letters, digits or hyphens.
- Labels can be concatenated with dots to form paths within the name space. Absolute paths, ending at the virtual root node, end with a trailing dot. All other paths which do not end with a trailing dot are relative paths.

May 17, 2019 280 / 440

• The overall length of a domain name is limited to 255 bytes.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

DNS Internationalization

Jürgen Schönwälder (Jacobs University Bremen)

- Recent efforts did result in proposals for Internationalized Domain Names in Applications (IDNA) (RFC 5890, RFC 5891, RFC 3492).
- The basic idea is to support internationalized character sets within applications.
- For backward compatibility reasons, internationalized character sets are encoded into 7-bit ASCII representations (ASCII Compatible Encoding, ACE).
- ACE labels are recognized by a so called ACE prefix. The ACE prefix for IDNA is xn--.
- A label which contains an encoded internationalized name might for example be the value xn--de-jg4avhby1noc0d.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 282/440

Resource Records

- Resource Records (RRs) hold typed information for a given name.
- Resource records have the following components:
 - The *owner* is the domain name which identifies a resource record.
 - The *type* indicates the kind of information that is stored in a resource record.
 - The *class* indicates the protocol specific name space, normally IN for the Internet.
 - The *time to life* (TTL) defines how many seconds information from a resource record can be stored in a local cache.
 - The data format (RDATA) of a resource records depends on the type of the resource record.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 283/440

Resource Record Types

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

Type	Description
А	IPv4 address
AAAA	IPv6 address
CNAME	Alias for another name (canonical name)
HINFO	Identification of the CPU and the operating system (host info)
TXT	Some arbitrary (ASCII) text
MX	List of mail server (mail exchanger)
NS	Identification of an authoritative server for a domain
PTR	Pointer to another part of the name space
SOA	Start and parameters of a zone (start of zone of authority)
RRSIG	Resource record signature
DNSKEY	Public key associated with a name
DS	Delegation signer resource record
NSEC	Next secure resource
SRV	Service record (generalization of the MX record)

The dig command line utility can be used to query the DNS. The following query retrieves any (all) resource records for instagram.com. and it is send to the DNS server at the IPv6 address 2001:4860:4860::8888:

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 285/440

DNS Message Formats

Jürgen Schönwälder (Jacobs University Bremen)

- A DNS message starts with a protocol header. It indicates which of the following four parts is present and whether the message is a query or a response.
- The header is followed by a list of questions.
- The list of questions is followed by a list of answers (resource records).

Computer Networks '2019

- The list of answers is followed by a list of pointers to authorities (also in the form of resource records).
- The list of pointers to authorities is followed by a list of additional information (also in the form of resource records). This list may contain for example A resource records for names in a response to an MX query.

May 17, 2019 286 / 440

DNS Message Header

Jürgen Schönwälder (Jacobs University Bremen)

0	1	2	3	4	-	-	7	-	9	-	1	2	3	4	5
i							ID								i
+		++ Opo	ode	Ī.		TCI	RD	RA	+ Z				RCO		+
++-++-++-++-++-++-++-++-++-++-+++++++															
ANCOUNT															
NSCOUNT															
+	+	++	·+ ·+	+ +	+ +		+ RCO +			+ +	+ +	+	+	+	++ +

- Simple DNS queries usually use UDP as a transport. UDP provides low overhead, which is important for resolvers that may need to contact many DNS servers.
- For larger data transfers (e.g., zone transfers), DNS may utilize TCP. DNS has been designed to support both UDP and TCP, leaving the choice to the client.

The DNS message header is defined in RFC 1035 [28]. The header fields have the following meaning:

Computer Networks '2019

May 17, 2019 287 / 440

- The ID field carries an identifier that is used by the sender of a query to associate a response message to a previous query.
- The QR bit specifies whether the message is a query or a response.
- The Opcode field specifies the type of query.
- The AA bit indicates whether a response is authoritative or not.
- The TC bit indicates whether the messages was truncated or not.
- The RD bit indicates if recursion is requested or not.
- The RA bit indicates whether recursive query support is available in the name server.
- The z bit is reserved for future use (zero).
- The AD bit indicates that the data included has been verified by the server providing it (authentic data).
- The CD bit indicates indicates in a query that non-verified data is acceptable (checking disabled).
- The RCODE field indicates whether a query was processed successfully or which error did occur during query processing.
- The QCOUNT field indicates the number of entries in the question section.
- The ANCOUNT field indicates the number of entries in the answer section.
- The NSCOUNT field indicates the number of entries in the authority records section.
- The ARCOUNT field indicates the number of entries in the additional records section.

DNS Question Format

	0 0										1 0					
:	+++++++++++++															
+++++++++++++																
+	+++++++++++++											+				
+++++++++++++																

- The query name carries the name for which information is requested.
- The query type indicate which information for the name is requested.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

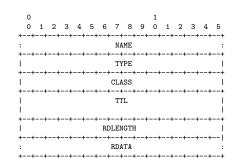

• The query class is effectively a constant in the Internet. (DNS was designed to support multiple networking technologies.)

While the format seems to indicate that a query can carry multiple questions, this is practically not supported. The main reason is that multiple questions would require multiple RCODEs since, i.e., some of the common header fields would have to be question specific.

May 17, 2019 288 / 440

This limitation is quite unfortunate. For example, to resolve a name to both an IPv4 address and an IPv6 address, it is necessary to send two queries.

DNS Answer, Authority, and Additional Section Format

• The TTL field indicates how long the response record is valid.

Jürgen Schönwälder (Jacobs University Bremen)

• The RDLENGTH field indicates the length of the type specific data contained in the RDATA field.

Computer Networks '2019

May 17, 2019 289 / 440

While it may appear inefficient to carry the name in each response, this is not really a problem since DNS has a special way to encode and compress names. The encoding of a DNS name such as www.example.com is a sequence of length prefixed bytes: 3www7exmaple3com0.

Since the maximum length of a label is 64 bytes, the two highest bits of a length field are not set. This is used to introduce 'pointers': If the length byte has the two highest bits set, then the remaining bits together with the bits of the following byte indicate the offset from the beginning of the DNS message where the string continues.

Resource Record Formats

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- An A resource record contains an IPv4 address encoded in 4 bytes in network byte order.
- An AAAA resource record contains an IPv6 address encoded in 16 bytes in network byte order.
- A CNAME resource record contains a character string preceded by the length of the string encoded in the first byte.
- A HINFO resource record contains two character strings, each prefixed with a length byte. The first character string describes the CPU and the second string the operating system.
- A MX resource record contains a 16-bit preference number followed by a character string prefixed with a length bytes which contains the DNS name of a mail exchanger.

May 17, 2019 290 / 440

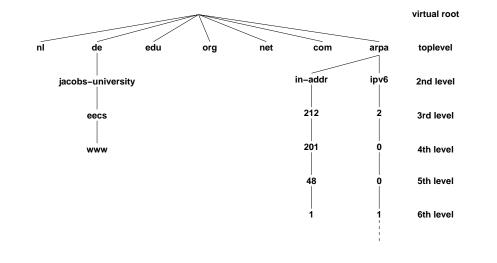

Resource Record Formats

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- A NS resource record contains a character string prefixed by a length byte which contains the name of an authoritative DNS server.
- A PTR resource record contains a character string prefixed with a length byte which contains the name of another DNS server. PTR records are used to map IP addresses to names (so called reverse lookups). For an IPv4 address of the form d₁.d₂.d₃.d₄, a PTR resource record is created for the pseudo domain name d₄.d₃.d₂.d₁.in addr.arpa. For an IPv6 address of the form h₁h₂h₃h₄ : . . . : h₁₃h₁₄h₁₅h₁₆, a PTR resource record is created for the pseudo domain name domain name h₁₆.h₁₅.h₁₄.h₁₃.. . . . h₄.h₃.h₂.h₁.ip6.arpa

DNS Reverse Trees

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 292 / 440

Resource Record Formats

- A SOA resource record contains two character strings, each prefixed by a length byte, and five 32-bit numbers:
 - Name of the DNS server responsible for a zone.
 - Email address of the administrator responsible for the management of the zone.
 - Serial number (SERIAL) (must be incremented whenever the zone database changes).
 - Time which may elapse before cached zone information must be updated (REFRESH).
 - Time after which to retry a failed refresh (RETRY).
 - Time interval after which zone information is considered not current anymore (EXPIRE).
 - Minimum lifetime for resource records (MINIMUM).

34 Creative Usage

DNS Security

Jürgen Schönwälder (Jacobs University Bremen)

- DNS security (DNSSEC) provides data integrity and authentication to security aware resolvers and applications through the use of cryptographic digital signatures.
- The Resource Record Signature (RRSIG) resource record stores digital signatures.
- The DNS Public Key (DNSKEY) resource record can be used to store public keys in the DNS.
- The Delegation Signer (DS) resource record simplifies some of the administrative tasks involved in signing delegations across organizational boundaries.

May 17, 2019 295 / 440

• The Next Secure (NSEC) resource record allows a security-aware resolver to authenticate a negative reply for either name or type non-existence.

Computer Networks '2019

Dynamic DNS Updates

- RFC 2136 / RFC 3007 define a mechanism which allows to dynamically update RRs on name server.
- This is especially useful in environments which use dynamic IP address assignments.
- The payload of a DNS update message contains
 - the zone section,
 - the prerequisite section (supporting conditional updates),
 - the update section, and
 - an additional data section.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

• The nsupdate command line utility can be used to make manual updates. Some DHCP servers perform automatic updates when they hand out an IP address.

May 17, 2019 296 / 440

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 297/440

DNS and Anycasting

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- DNS servers often make use of IP anycasting in order to improve availability and performance
 - Several DNS service instances with the same IP address are deployed
 - The IP routing system determines to which service instance a specific DNS request is routed
- Many of the DNS root servers ([a-m].root-servers.org) use anycasts; the number of DNS service instances was reported to be above 600 in October 2016
- Anycasting works well for a simple stateless request / response protocol like DNS, see RFC 7094 and RFC 4786 for further details on IP anycasts

May 17, 2019 298 / 440

DNS and Service Load Balancing

Jürgen Schönwälder (Jacobs University Bremen)

- Content Delivery Networks (CDN) sometimes use short lived DNS answers to direct requests to servers close to the requester.
- An underlying assumption is that the recursive resolver used by a host is located close to the host (in terms of network topology).
- This assumption is not generally true, for example, if hosts use generic recursive resolvers like Google's public DNS resolver (8.8.8.8 or 2001:4860:4860::8888), see also https://www.xkcd.com/1361/.
- DNS extensions have been defined to allow a recursive resolver to indicate a client subnet in a DNS request so that DNS servers can provide responses that match the location of the host, see RFC 7871 for further details.

May 17, 2019 299 / 440

Computer Networks '2019

Kaminsky DNS Attack

- Cache poisoning attack ('2008):
 - Cause applications to generate queries for non-existing names such as aaa.example.net, aab.example.net, etc.
 - Send fake responses quickly, trying to guess the 16-bit query ID number.
 - In the fake responses, include additional records that overwrite A records for lets say example.net.
- Counter measure:
 - Updated DNS libraries use random port numbers.
 - An attacker has to guess a 16-bit ID number and in addition the 16-bit port number.
- The real solution is DNSSEC

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 300 / 440

DNS as DDoS Amplifier

Jürgen Schönwälder (Jacobs University Bremen)

- DNS queries with a spoofed source address can be used to direct responses from open resolvers to a certain attack target; the DNS resolver thus helps to hide (to some extend) the source of the attack.
- Since DNS responses are typically larger than DNS queries, a DNS resolver also acts as an amplifier, turning, for example, 100Mbps query traffic into 1Gbps attack traffic.
- DNS security makes amplification significantly more effective if cryptographic algorithms are used that require relatively long keys.

Computer Networks '2019

• It has been shown that elliptic curve algorithms tend to be way more space efficient than traditional RSA algorithms.

May 17, 2019 301 / 440

DNS Blacklists

- DNS Blacklists store information about bad behaving hosts.
- Originally used to publish information about sites that originated unsolicited email (spam).
- If the IP address 192.0.2.99 is found guilty to emit spam, a DNS Blacklists at bad.example.com will add the following DNS records:
 99.2.0.192.bad.example.com IN A 127.0.0.2
 99.2.0.192.bad.example.com IN TXT "Spam received."
- A mail server receiving a connection from 192.0.2.99 may lookup the A record of 99.2.0.192.bad.example.com and if it has the value 127.0.0.2 decline to serve the client.
- For more details, see RFC 5782.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 302 / 440

DNS Backscatter, Stalking, Tunnels, Command and Control, ...

- Kensuke Fukuda has analyzed the DNS traffic generated by middleboxes when they perform reverse lookups on IP addresses that they see (so called DNS backscatter).
- Geoff Huston placed advertisements on web pages that include one-time valid DNS names to drive certain measurements and they found that these one-time DNS names sometimes enjoy additional lookups from very different locations in the network weeks later (which he called stalking).
- Since DNS traffic is often not filtered, people have created many different techniques and tools to tunnel IP traffic over DNS.

Computer Networks '2019

May 17, 2019 303 / 440

Jürgen Schönwälder (Jacobs University Bremen)

• It has been reported that DNS has seen some usage as a command and control channel for malware and botnets.

DNS over TLS, DTLS, or HTTPS

- RFC 7858 defines how DNS messages can be sent over Transport Layer Security (TLS)
- RFC 8094 defines how DNS messages can be sent over Datagram Transport Layer Security (DTLS)
- RFC 8484 defined how to send DNS queries over HTTPS. Each DNS query-response pair is mapped into an HTTP exchange.
- The protocol defined in RFC 8484 uses the traditional DNS message encoding format.
- RFC 8427 provides a specification for the representation of DNS messages as JSON objects.
- Finally, RFC 8499 defines an updated DNS terminology.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

• The motivation behind all these specifications is to enhance the privacy of DNS lookups.

May 17, 2019 304 / 440

Part IX

Augmented Backus Naur Form (ABNF)

Several application protocols use a textual encoding of protocol messages. A text-based encoding of protocol messages has the advantage that messages are "programmer readable". The downside of text-based encodings of protocol messages is that encodings usually are less efficient (both in terms of the size of the messages as well as the encoding/decoding processing time).

For the text-based encoding of protocol messages, it is useful to formally specify the format of wellformed protocol messages. This is commonly done by specifying a grammar for the set of well-formed protocol messages. ABNF is a formalism for writing down such grammars.

Section 35: Basics, Rule Names, Terminal Symbols

- Basics, Rule Names, Terminal Symbols
- **36** Operators
- **37** Core Definitions
- **38** ABNF in ABNF

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 308 / 440

ABNF Basics

- The Augmented Backus Naur Form (ABNF) defined in RFC 5234 can be used to formally specify textual protocol messages.
- An ABNF definition consists of a set of rules (sometimes also called productions).
- Every rule has a name followed by an assignment operator followed by an expression consisting of terminal symbols and operators.
- The end of a rule is marked by the end of the line or by a comment. Comments start with the comment symbol ; (semicolon) and continue to the end of the line.
- ABNF does not define a module concept or an import/export mechanism.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

ABNF, as defined in RFC 5234 [10], was originally part of the Internet email standards. It has been later factored out since ABNF is useful for many other protocols that use textual message formats.

May 17, 2019 309 / 440

ABNF is a special version of a Backus Naur Form for describing context-free grammars. A specific difference of ABNF to more regular Backus–Naur forms is that ABNF is specific how terminal symbols are encoded.

Rule Names and Terminal Symbols

Jürgen Schönwälder (Jacobs University Bremen)

- The name of a rule must start with an alphabetic character followed by a combination of alphabetics, digits and hyphens. The case of a rule name is not significant.
- Terminal symbols are non-negative numbers. The basis of these numbers can be binary (b), decimal (d) or hexadecimal (x). Multiple values can be concatenated by using the dot . as a value concatenation operator. It is also possible to define ranges of consecutive values by using the hyphen – as a value range operator.
- Terminal symbols can also be defined by using literal text strings containing US ASCII characters enclosed in double quotes. Note that these literal text strings are case-insensitive.

May 17, 2019 310 / 440

Computer Networks '2019

Simple ABNF Examples

CR = %d13	; ASCII carriage return code in decimal
CRLF = %d13.10	; ASCII carriage return and linefeed code sequence
DIGIT = %x30-39	; ASCCI digits (0 - 9)
ABA = "aba"	; ASCII string "aba" or "ABA" or "Aba" or
abba = %x61.62.62.61	; ASCII string "abba"

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 311 / 440

ABFN Case-Sensitive String Support

- RFC 7405 adds support for case-sensitive strings.
 - %s = case-sensitive string
 - %i = case-insensitive string

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Examples:
 - r1 = "aBc"
 - r2 = %i"aBc"
 - r3 = %s"aBc"

The rules r1 and r2 are equivalent and they will both match "abc", "Abc", "aBc", "aBC", "aBC", "ABc", "aBC", "ABC", and "ABC". The rule r3 matches only "aBc".

May 17, 2019 312 / 440

The case sensitive string support defined in RFC 7405 [26] is useful in situations where case insensitive string constants are not desired. (Essentially newer protocols that will never run on hardware that only supports uppercase or lowercase characters.)

Section 36: Operators

Basics, Rule Names, Terminal Symbols

- **37** Core Definitions
- **38** ABNF in ABNF

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 313/440

ABFN Operators

- Concatenation
 - Concatenation operator symbol is the empty word
 - Example: abba = %x61 %x62 %x62 %x61
- Alternatives
 - Alternatives operator symbol is the forward slash /
 - Example: aorb = %x61 / %x62
 - Incremental alternatives assignment operator =/ can be used for long lists of alternatives
- Grouping
 - Expressions can be grouped using parenthesis
 - A grouped expression is treated as a single element
 - Example: abba = %x61 (%x62 %x62) %x61

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 314 / 440

ABFN Operators

- Repetitions
 - The repetitions operator has the format n*m where n and m are optional decimal values
 - The value of n indicates the minimum number of repetitions (defaults to 0 if not present)
 - The value m indicates the maximum number of repetitions (defaults to infinity if not present)
 - The format * indicates 0 or more repetitions
 - Example: abba = %x61 2 %x62 %x61

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Optional
 - Square brackets enclose an optional element
 - Example: [ab] ; equivalent to *1(ab)

May 17, 2019 315 / 440

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 321/440

Part X Electronic Mail (SMTP, MIME, IMAP, SIEVE)

Electronic mail (email) is a method of exchanging messages between people using electronic devices. Email appeared in the 1960s and by the mid-1970s had taken the form now recognized as email. Email deliver in the early days could take hours or days. Today's email systems use a store-and-forward model where messages are repeatedly stored and forwarded until they have reached the receiver's mailbox. Transient failures of systems may cause delivery delays but usually do not lead to a loss of messages.

We focus on the Internet email system. The central protocols are the Simple Mail Transfer Protocol (SMTP) and the associated Internet Message Format. Like most protocols designed in the late 1970s and early 1980s, not much attention was given to security and privacy aspects.

Section 39: Components and Terminology

39 Components and Terminology

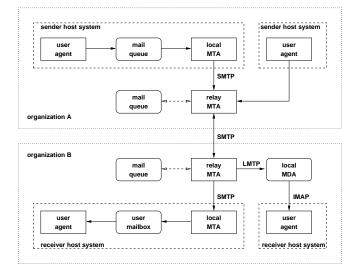

- **40** Simple Mail Transfer Protocol (SMTP)
- Multipurpose Internet Mail Extensions (MIME)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Internet Message Access Protocol (IMAP)
- Filtering of Messages (SIEVE)

May 17, 2019 323 / 440

Components Involved in Electronic Mail

Jürgen Schönwälder (Jacobs University Bremen)

Computer Networks '2019

May 17, 2019 324 / 440

Terminology

• Mail User Agent (MUA) - the source or targets of electronic mail

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Mail Transfer Agent (MTA) server and clients providing mail transport service
- Mail Delivery Agent (MDA) delivers mail messages to the receiver's mail box
- Store-and-Forward Principle mail messages are stored and then forwarded to another system; responsibility for a message is transferred once it is stored again
- Envelope vs. Header vs. Body mail messages consist of a header and a body; the transfer of mail message is controlled by the envelope (which might be different from the header)

May 17, 2019 325 / 440

Section 40: Simple Mail Transfer Protocol (SMTP)

- **39** Components and Terminology
- **40** Simple Mail Transfer Protocol (SMTP)
- **41** Multipurpose Internet Mail Extensions (MIME)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Internet Message Access Protocol (IMAP)
- Filtering of Messages (SIEVE)

May 17, 2019 326 / 440

Simple Mail Transfer Protocol (SMTP)

- Defined in RFC 5321 (originally RFC 821)
- Textual client/server protocol running over TCP (default port 25)
- Small set of commands to be executed by an SMTP server
- Supports multiple mail transactions over a single transport layer connection
- Server responds with structured response codes

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

• Message formats specified in ABNF

The SMTP protocol is one on the old classic Internet protocols. The first version was published in RFC 821 [37] in 1982. The current version is defined in RFC 5321 [22], which appeared in 2008. In the early days of the Internet, there were many email systems out there and there was a big need to interwork with other email systems.

May 17, 2019 327 / 440

SMTP Commands

Command	Description
HELO	Indentify clients to a SMTP server (HELLO)
EHLO	Extended identification (EXTENDED HELLO)
MAIL	Inititate a mail transaction (MAIL)
RCPT	Identity an individual recipient (RECIPIENT)
DATA	Transfer of mail message (DATA)
RSET	Aborting current mail transaction (RESET)
VRFY	Verify an email address (VERIFY)
EXPN	Expand a mailing list address (EXPAND)
HELP	Provide help about SMTP commands (HELP)
NOOP	No operation, has no effect (NOOP)
QUIT	Ask server to close connection (QUIT)

Here is the transcript of an example session with a mail server (sending a fake email). We first lookup the mail exchanger for our target domain:

May 17, 2019 328 / 440

\$ dig +short mx example.com. 20 mx1.example.com 20 mx2.example.com 20 mx3.example.com

We randomly pick an address (if there are multiple addresses with the same priority) and start a TCP connection to port 25:

\$ nc mx2.example.com. 25
220 mx2.example.com. ESMTP Postfix EHLO hacker.com 250-mx2.example.com 250-PIPELINING 250-SIZE 102400000 250-VRFY 250-ETRN 250-STARTTLS 250-ENHANCEDSTATUSCODES 250-8BITMIME 250 DSN MAIL FROM: <j.luser@fakemail.com> 250 2.1.0 Ok RCPT TO: <joe.researcher@example.com> 250 2.1.5 Ok DATA 354 End data with <CR><LF>.<CR><LF> From: A. Turing <a.turing@award.com> To: <joe.researcher@example.com> Subject: your turing award Date: Mon, 30 Apr 2018 10:01:04 +0200

Dear outstanding researcher,

I am delighted to announce that you will receive this year's Alan Turing award for your outstanding research. To participate at the ceremony, please pay 3.000 Euro for the award processing and the travel arrangements.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

Alan Turing

250 2.0.0 from MTA(smtp:[2001:db8::42]:10031): 250 2.0.0 Ok: queued as F39AC6CF QUIT 221 2.0.0 Bye

SMTP in ABNF (excerpt)

```
helo = "HELO" SP Domain CRLF
ehlo = "EHLO" SP Domain CRLF
mail = "MAIL FROM:" ("<>" / Reverse-Path) [SP Mail-Parameters] CRLF
rcpt = "RCPT TO:" ("<Postmaster@" domain ">" / "<Postmaster>" /
Forward-Path) [SP Rcpt-Parameters CRLF
data = "DATA" CRLF
rset = "RSET" CRLF
vrfy = "VRFY" SP String CRLF
expn = "EXPN" SP String CRLF

noop = "NOOP" [ SP String ] CRLF
quit = "QUIT" CRLF
```

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 329 / 440

Note that email addresses are written using angle brackets as delimiters. The correct writing of the email address j.user@example.org is therefore <joe.user@example.org>. Note that case does not matter, hence <Joe.User@example.org> is the same address as <joe.user@example.org>. (Since there is no real value in writing email addresses in mixed case, technical people tend to prefer writing email addresses with all characters in lowercase.)

Theory of 3 Digit Reply Codes

- The first digit denotes whether the response is good, bad or incomplete.
 - 1yz Positive Preliminary reply
 - 2yz Positive Completion reply
 - 3yz Positive Intermediate reply
 - 4yz Transient Negative Completion reply
 - 5yz Permanent Negative Completion reply

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- The second digit encodes responses in specific categories.
- The third digit gives a finer gradation of meaning in each category specified by the second digit.

The three digit reply codes promote extensibility of the SMTP protocol. If new error codes are introduced (see for example RFC 7504 [23]), then old implementations that do not understand the precise semantics can still behave sensible if the semantics of the first or second digit is understood.

May 17, 2019 330 / 440

Internet Message Format

- The format of Internet messages is defined in RFC 5322.
- Most important ABNF productions and messages fields:

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

```
fields = *(trace *resent-field) *regular-field
resend-field = resent-date / resent-from / resent-sender
resend-field =/ resent-to / resent-cc / resent-bcc
resend-field =/ resent-msg-id
regular-field = orig-date / from / sender
regular-field =/ reply-to / to / cc / bcc
regular-field =/ message-id / in-reply-to / references
regular-field =/ subject / comments / keywords
```

 Note that fields such as to or cc may be different from the actual addresses used by SMTP commands (the envelope).

May 17, 2019 331 / 440

Originator Fields

• The From: field specifies the author(s) of the message.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

from = "From:" mailbox-list CRLF

• The Sender: field specifies the mailbox of the sender in cases where the actual sender is not the author (e.g., a secretary).

sender = "Sender:" mailbox CRLF

• The Reply-To: field indicates the mailbox(es) to which the author of the message suggests that replies be sent.

reply-to = "Reply-To:" address-list CRLF

May 17, 2019 332 / 440

Destination Address Fields

• The To: field contains the address(es) of the primary recipient(s) of the message.

to = "To:" address-list CRLF

• The Cc: field (Carbon Copy) contains the addresses of others who are to receive the message, though the content of the message may not be directed at them.

cc = "Cc:" address-list CRLF

• The Bcc: field (Blind Carbon Copy) contains addresses of recipients of the message whose addresses are not to be revealed to other recipients of the message.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 333/440

bcc = "Bcc:" (address-list / [CFWS]) CRLF

Identification and Origination Date Fields

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

• The Message-ID: field provides a unique message identifier that refers to a particular version of a particular message.

message-id = "Message-ID:" msg-id CRLF

• The In-Reply-To: field will contain the contents of the Message-ID: field of the message to which this one is a reply.

in-reply-to = "In-Reply-To:" 1*msg-id CRLF

• The References: field will contain the contents of the parent's References: field (if any) followed by the contents of the parent's Message-ID: field (if any).

references = "References:" 1*msg-id CRLF

May 17, 2019 334 / 440

Informational Fields

• The Subject: field contains a short string identifying the topic of the message.

subject = "Subject:" unstructured CRLF

• The Comments: field contains any additional comments on the text of the body of the message.

comments = "Comments:" unstructured CRLF

• The Keywords: field contains a comma-separated list of important words and phrases that might be useful for the recipient.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

keywords = "Keywords:" phrase *("," phrase) CRLF

May 17, 2019 335 / 440

Trace Fields

• The Received: field contains a (possibly empty) list of name/value pairs followed by a semicolon and a date-time specification. The first item of the name/value pair is defined by item-name, and the second item is either an addr-spec, an atom, a domain, or a msg-id.

received = "Received:" name-val-list ";" date-time CRLF

• The Return-Path: field contains an email address to which messages indicating non-delivery or other mail system failures are to be sent.

return = "Return-Path:" path CRLF

• A message may have multiple received fields and the return field is optional

trace = [return] 1*received

May 17, 2019 336 / 440

Trace fields are important for troubleshooting email delivery problems. They are usually not shown to the user (unless the user wishes to see them.)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

Resend Fields

- Resent fields are used to identify a message as having been reintroduced into the transport system by a user.
- Resent fields make the message appear to the final recipient as if it were sent directly by the original sender, with all of the original fields remaining the same.
- Each set of resent fields correspond to a particular resending event.

resent-date = "Res	ent-Date:" date-time CRLF
resent-from = "Rese	nt-From:" mailbox-list CRLF
resent-sender = "Re	sent-Sender:" mailbox CRLF
resent-to = "Rese	nt-To:" address-list CRLF
resent-cc = "Rese	nt-Cc:" address-list CRLF
resent-bcc = "Resent-Bcc	:" (address-list / [CFWS]) CRLF
resent-msg-id = "Res	ent-Message-ID:" msg-id CRLF
Jürgen Schönwälder (Jacobs University Bremen) Compu	ter Networks '2019 May 17, 2019 337 / 440

The resens mechanism, though sometimes very useful, often tends to confuse people.

Internet Message Example

Date: Tue, 1 Apr 1997 09:06:31 -0800 (PST) From: coyote@desert.example.org To: roadrunner@acme.example.com Subject: I have a present for you

Look, I'm sorry about the whole anvil thing, and I really didn't mean to try and drop it on you from the top of the cliff. I want to try to make it up to you. I've got some great birdseed over here at my place--top of the line stuff--and if you come by, I'll have it all wrapped up for you. I'm really sorry for all the problems I've caused for you over the years, but I know we can work this out.

Wile E. Coyote "Super Genius" coyote@desert.example.org

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 338 / 440

This example is taken from RFC 5228 [16]. Additional examples for mail messages can be found in Appendix A of RFC 5322 [39].

Section 41: Multipurpose Internet Mail Extensions (MIME)

- **39** Components and Terminology
- **40** Simple Mail Transfer Protocol (SMTP)
- **41** Multipurpose Internet Mail Extensions (MIME)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Internet Message Access Protocol (IMAP)
- Filtering of Messages (SIEVE)

May 17, 2019 339 / 440

Multipurpose Internet Mail Extensions

- The Multipurpose Internet Mail Extensions (MIME) defines conventions to
 - support multiple different character sets;
 - support different media types;
 - support messages containing multiple parts;

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- $\bullet\,$ encode content compatible with RFC 5321 and RFC 5322.
- The set of media types and identified characters sets is extensible.
- MIME is widely implemented and not only used for Internet mail messages.

May 17, 2019 340 / 440

MIME Header Fields

• The MIME-Version: field declares the version of the Internet message body format standard in use.

version = "MIME-Version:" 1*DIGIT "." 1*DIGIT CRLF

• The Content-Type: field specifies the media type and subtype of data in the body.

content = "Content-Type:" type "/" subtype *(";" parameter)

• The Content-Transfer-Encoding: field specifies the encoding transformation that was applied to the body and the domain of the result.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

encoding = "Content-Transfer-Encoding:" mechanism

May 17, 2019 341 / 440

MIME Header Fields

• The optional Content-ID: field allows one body to make reference to another.

id = "Content-ID:" msg-id

• The optional Content-Description: field associates some descriptive information with a given body.

description = "Content-Description" *text

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 342/440

MIME Media Types

- Five discrete top-level media types (RFC 2046):
 - text
 - image
 - audio
 - video
 - application
- Two composite top-level media types (RFC 2046):

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- multipart
- message
- Some media types have additional parameters (e.g., the character set).
- The Internet Assigned Numbers Authority (IANA) maintains a list of registered media types and subtypes.

May 17, 2019 343 / 440

MIME Boundaries

Jürgen Schönwälder (Jacobs University Bremen)

- Multipart documents consists of several entities which are separated by a boundary delimiter line.
- After its boundary delimiter line, each body part then consists of a header area, a blank line, and a body area.
- The boundary is established through a parameter of the Content-Type: header field of the message.

Content-Type: multipart/mixed; boundary="gc0pJq0M:08jU534c0p"

• The boundary delimiter consists of two dashes followed by the established boundary followed by optional white space and the end of the line. The last boundary delimiter contains two hyphens following the boundary.

--gc0pJq0M:08jU534c0p

May 17, 2019 344 / 440

• The boundary delimiter must chosen so as to guarantee that there is no clash with the content.

Computer Networks '2019

332

MIME Example

From: Nathaniel Borenstein <nsb@bellcore.com> To: Ned Freed <ned@innosoft.com> Date: Sun, 21 Mar 1993 23:56:48 -0800 (PST) Subject: Sample message MIME-Version: 1.0 Content-type: multipart/mixed; boundary="simple boundary" This is the preamble. It is to be ignored. --simple boundary

This is implicitly typed plain US-ASCII text. It does NOT end with a linebreak. --simple boundary Content-type: text/plain; charset=us-ascii

This is explicitly typed plain US-ASCII text ending with a linebreak.

--simple boundary--

This is the epilogue. It is also to be ignored.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 345 / 440

Base64 Encoding

- Idea: Represent three input bytes (24 bit) using four characters taken from a 6-bit alphabet.
- The resulting character sequence is broken into lines such that no line is longer than 76 characters if the base64 encoding is used with MIME.
- If the input text has a length which is not a multiple of three, then the special character = is appended to indicate the number of fill bytes.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

• Base64 encoded data is difficult to read by humans without tools (which however are trivial to write).

May 17, 2019 346 / 440

Base64 Character Set

Value	Encoding	Value	Encoding	Value	Encoding	Value	Encoding
	A	17	•	34	•	51	-
1	В	18	S	35	j	52	0

Section 42: Internet Message Access Protocol (IMAP)

- **B** Components and Terminology
- **40** Simple Mail Transfer Protocol (SMTP)
- **41** Multipurpose Internet Mail Extensions (MIME)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Internet Message Access Protocol (IMAP)
- Filtering of Messages (SIEVE)

May 17, 2019 349 / 440

Internet Message Access Protocol (IMAP)

Jürgen Schönwälder (Jacobs University Bremen)

- The Internet Message Access Protocol (IMAP) defined in RFC 3501 allows a client to access and manipulate electronic mail messages stored on a server.
- Messages are stored in mailboxes (message folders) which are identified by a mailbox name.
- IMAP runs over TCP with the well-known port number 143.
- IMAP users are typically authenticated using passwords (transmitted in cleartext over TCP).
- It is strongly suggested to use the Transport Layer Security (TLS) option to encrypt authentication exchanges and message transfers.

Computer Networks '2019

May 17, 2019 350 / 440

IMAP Message Identification

• Messages in a mailbox are identified by numbers:

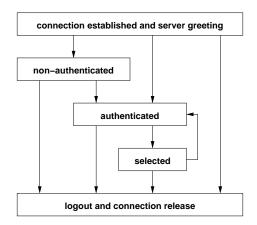

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- The *unique identifier* identifies a message in a mailbox independent of its position. Unique identifiers should remain persistent across IMAP sessions.
- The *message sequence number* is the relative position of a message in a mailbox. The first position in a mailbox is 1.
- Persistency of the unique identifier can only be achieved to a certain extend and implementation therefore must cope with non-persistent unique identifiers.

May 17, 2019 351 / 440

IMAP States

Jürgen Schönwälder (Jacobs University Bremen)

Computer Networks '2019

• The state determines the set of applicable commands.

May 17, 2019 352 / 440

IMAP Commands

- Commands applicable in all states:

 CAPABILITY
 NOOP
 LOGOUT

 Reports the server's capabilities
 Empty command (may be used to trigger status updates)
 Terminate the IMAP session
- Commands applicable in the *non-authenticated* state: AUTHENTICATE LOGIN STARTLS Indicates an authentication mechanism to the server Trivial authentication with a cleartext password Start TLS negotation to protect the channel
- Note that the completion of the STARTTLS command can change the capabilities announced by the server.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 353/440

IMAP Commands

• Commands applicable in the *authenticated* state:

Communation (
SELECT	Select an existing mailbox (read-write)
EXAMINE	Select an existing mailbox (read-only)
CREATE	Create a new mailbox
DELETE	Delete an existing mailbox
RENAME	Rename an existing mailbox
SUBSCRIBE	Add a mailbox to the server's list of active mailboxes
UNSUBSCRIBE	Remove a mailbox from the server's list of active mailboxes
LIST	List all existing mailboxes
LSUB	List all active mailboxes
STATUS	Retrieve the status of a mailbox
APPEND	Append a message to a mailbox

• The SELECT and EXAMINE commands cause a transition into the *selected* state.

IMAP commands are defined in ABNF. Here is an excerpt of the definitions. For details, see RFC 3501
INAL Commands are defined in ADM. There is an excerpt of the definitions. For details, see the 0.5001
[9].

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 354 / 440

tag	=	1* <any "+"="" atom_char="" except=""></any>
command	=	<pre>tag SPACE (command_any / command_auth / command_nonauth / command_select) CRLF ;; Modal based on state</pre>
command_any	=	"CAPABILITY" / "LOGOUT" / "NOOP" / x_command ;; Valid in all states
command_auth	=	<pre>append / create / delete / examine / list / lsub / rename / select / status / subscribe / unsubscribe ;; Valid only in Authenticated or Selected state</pre>
command_nonauth	=	login / authenticate ;; Valid only when in Non-Authenticated state
command_select	=	"CHECK" / "CLOSE" / "EXPUNGE" / copy / fetch / store / uid / search ;; Valid only when in Selected state

IMAP Commands

- Commands applicable in the *selected* state: CHECK Create a copy of the current mailbox (checkpoint) CLOSE Close the current mailbox and leave state EXPUNGE Expunge all messages marked as deleted Search for messages matching given criteria SEARCH Fetch data of a message in the current mailbox FETCH STORE Store data as a message in the current mailbox Copy a message to the en of the specified mailbox COPY UID Execute a command using unique identifiers
- The CLOSE command causes a transition back into the *authenticated* state.

Jürgen Schönwälder (Jacobs University Bremen)	Computer Networks '2019	May 17, 2019	355 / 440

IMAP responses are defined in ABNF as well. Here is an excerpt of the definitions. For details, see RFC 3501 [9].

response	= *(continue_req / response_data) response_done
continue_req	= "+" SPACE (resp_text / base64)
response_data	<pre>= "*" SPACE (resp_cond_state / resp_cond_bye / mailbox_data / message_data / capability_data) CRLF</pre>
response_done	<pre>= response_tagged / response_fatal</pre>
response_fatal	<pre>= "*" SPACE resp_cond_bye CRLF ;; Server closes connection immediately</pre>
response_tagged	<pre>= tag SPACE resp_cond_state CRLF</pre>

IMAP Tagging

- IMAP supports asynchronous, concurrent operations. A client can send multiple commands which the server will execute asynchronously.
- A client tags commands such that responses returned by the server can be related to previously sent commands.
- Server responses
 - that do not indicate command completion are prefixed with the token *;
 - that request additional information to complete a command are prefixed with the token +;
 - that communicate the successful for unsuccessful completion of a comment are prefixed with the tag.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 356 / 440

344

Section 43: Filtering of Messages (SIEVE)

- **B** Components and Terminology
- **40** Simple Mail Transfer Protocol (SMTP)
- **41** Multipurpose Internet Mail Extensions (MIME)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Internet Message Access Protocol (IMAP)
- **43** Filtering of Messages (SIEVE)

May 17, 2019 357 / 440

SIEVE Filtering Language

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- The SIEVE language defined in RFC 5228 can be used to filter messages at time of final delivery.
- The language can be implemented either on the mail client of the mail server.
- SIEVE is extensible, simple, and independent of the access protocol, mail architecture, and operating system.
- The SIEVE language can be safely executed on servers (such as IMAP servers) as it has no variables, loops, or ability to shell out to external programs.

May 17, 2019 358 / 440

SIEVE Scripts

• SIEVE scripts are sequences of commands.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- An *action command* is an identifier followed by zero or more arguments, terminated by a semicolon. Action commands do not take tests or blocks as arguments.
- A *control command* is similar, but it takes a test as an argument, and ends with a block instead of a semicolon.
- A *test command* is used as part of a control command. It is used to specify whether or not the block of code given to the control command is executed.
- The empty SIEVE script keeps the message (implicit keep).

May 17, 2019 359 / 440

```
SIEVE is defined in ABNF as well. Here is an excerpt of the definitions. For details, see RFC 5228 [16].
command = identifier arguments ( ";" / block )
commands = *command
identifier = (ALPHA / "_") *(ALPHA / DIGIT / "_")
argument = string-list / number / tag
arguments = *argument [test / test-list]
block = "{" commands "}"
start = commands
string = quoted-string / multi-line
string-list = "[" string *("," string) "]" / string
;; if there is only a single string, the brackets are optional
test = identifier arguments
test-list = "(" test *("," test) ")"
```

SIEVE Example

```
# Declare any optional features or extension used by the script
require ["fileinto", "reject"];
# Reject any large messages (note that the four leading dots get
# "stuffed" to three)
if size :over 1M {
       reject text:
Please do not send me large attachments.
Put your file on a server and send me the URL.
Thank you.
.... Fred
.
;
        stop;
}
```

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 360 / 440

SIEVE Example (cont.)

```
# Move messages from IETF filter discussion list to filter folder
if header :is "Sender" "owner-ietf-mta-filters@imc.org" {
      fileinto "filter"; # move to "filter" folder
      stop;
}
#
# Keep all messages to or from people in my company
#
stop;
}
```

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 361/440

SIEVE Example (cont.)

```
# Try and catch unsolicited email. If a message is not to me,
# or it contains a subject known to be spam, file it away.
#
header :matches "subject"
    ["*make*money*fast*", "*university*dipl*mas*"]) {
       # If message header does not contain my address,
       # it's from a list.
       fileinto "spam"; # move to "spam" folder
} else {
       # Move all other (non-company) mail to "personal" folder.
       fileinto "personal";
}
```

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 362 / 440

Part XI Hypertext Transfer Protocol (HTTP)

Hypertext Transfer Protocol (HTTP)

Jürgen Schönwälder (Jacobs University Bremen)

- HTTP version 1.0 was published in 1996 in RFC 1945.
- HTTP version 1.1 was originally defined in 1997 in RFC 2068 and later revised in 1999 in RFC 2616. It became one of the core building blocks of the World Wide Web. The latest revision is published in RFCs 7230-7235.
- HTTP was designed to retrieve and manipulate documents (resources) maintained on HTTP servers. The protocol runs on top of TCP and it uses the well known port number 80. It uses MIME conventions to distinguish different media types.
- RFC 2817 describes how to use TLS with HTTP 1.1. The secure version of HTTP uses the well known port number 443.
- HTTP version 2.0 was published in 2015 in RFC 7540. It supports multiple streams multiplexed over a single connection, it uses a binary encoding, and it enables servers to push data to clients.

Section 44: URLs, URNs, URIs, IRIs

44 URLs, URNs, URIs, IRIs

45 HTTP 1.1 Methods

46 HTTP 1.1 Features

47 HTTP 2.0

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 368 / 440

URL, URI, URN, IRI, ...

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Uniform Resource Identifier (URI) A URI is a sequence of characters from the US-ASCII for identifying an abstract or physical resource.
- Uniform Resource Locator (URL) The term URL refers to the subset of URIs that provide a means of locating the resource by describing its primary access mechanism (e.g., its network "location").
- Uniform Resource Name (URN) The term URN refer to the subset of URIs that identify resources by means of a globally unique and persistent name.
- Internationalized Resource Identifier (IRI) An IRI is a sequence of characters from the Universal Character Set for identifying an abstract or physical resource.

Section 45: HTTP 1.1 Methods

URLs, URNs, URIs, IRIs

45 HTTP 1.1 Methods

46 HTTP 1.1 Features

47 HTTP 2.0

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 375 / 440

HTTP 1.1 Methods

Method	Description
GET	Retrieve a resource identified by a URI
HEAD	Retrieve meta-information of a resource identified by a URI
POST	Annotate an existing resource by passing information to a resource
PUT	Store information under the supplied URI (may create a new resource)
DELETE	Delete the resource identified by the URI
OPTIONS	Request information about methods supported for a URI
TRACE	Application-layer loopback of request messages for testing purposes
CONNECT	Initiate a tunnel such as a TLS or SSL tunnel

- A client invokes a *method* on a *resource* by sending a *request message*
- A server returns a *response message*, which may include a *representation* of the accessed *resource*

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 376 / 440

Safe and Idempotent Methods

- Safe methods:
 - Safe methods are intended only for information retrieval and should not change the state of the server
 - Safe methods should not have side effects, beyond relatively harmless effects such as logging
 - The methods GET, HEAD, OPTIONS and TRACE are defined to be safe
- Idempotent methods:
 - Idempotent methods can be executed multiple times without producing results that are different form a single execution of the method
 - The methods PUT and DELETE are idempotent.
 - Safe methods should be idempotent as well

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 377 / 440

Method Properties

Method	Req Body	Res Body	Safe	Idempotent	Cacheable
GET	No	Yes	Yes	Yes	Yes
HEAD	No	No	Yes	Yes	Yes
POST	Yes	Yes	No	No	Yes
PUT	Yes	Yes	No	Yes	No
DELETE	No	Yes	No	Yes	No
OPTIONS	Opt	Yes	Yes	Yes	No
CONNECT	Yes	Yes	No	No	No
TRACE	Yes	Yes	Yes	Yes	No

• Supporting caches well is a fundamental goal of HTTP

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 380/440

Section 46: HTTP 1.1 Features

IRLS, URNS, URIS, IRIS

45 HTTP 1.1 Methods

46 HTTP 1.1 Features

47 HTTP 2.0

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 381/440

Persistent Connections and Pipelining

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- A client can establish a persistent connection to a server and use it to send multiple Request messages.
- HTTP relies on the MIME Content-Length header field to detect the end of a message body (document).
- Early HTTP versions allowed only a single Request/Response exchange over a single TCP connection, which is of course rather expensive.
- HTTP 1.1 also allows clients to make multiple requests without waiting for each response (pipelining), which can significantly reduce latency.

May 17, 2019 382 / 440

Chunked Transfer Encoding

- Supports streaming of data where the content length is initially not known
- Uses the Transfer-Encoding HTTP header in place of the Content-Length header

May 17, 2019 383 / 440

• Content is send in small chunks.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- The size of each chunk is sent right before the chunk itself.
- The end of the data transfer is indicated by a final chunk of length zero.

Caching and Proxies

Jürgen Schönwälder (Jacobs University Bremen)

- Probably the most interesting and also most complex part of HTTP is its support for proxies and caching.
- Proxies are entities that exist between the client and the server and which basically relay requests and responses.
- Some proxies and clients maintain caches where copies of documents are stored in local storage space to speedup future accesses to these cached documents.
- The HTTP protocol allows a client to interrogate the server to determine whether the document has changed or not.
- Not all problems related to HTTP proxies and caches have been solved. A good list of issues can be found in RFC 3143.

May 17, 2019 384 / 440

Computer Networks '2019

Negotiation

- Negotation can be used to select different document formats, different transfer encodings, different languages or different character sets.
- Server-driven negotiation begins with a request from a client (a browser). The client indicates a list of its preferences. The server then decides how to best respond to the request.
- Client-driven negotiation requires two requests. The client first asks the server what is available and then decides which concrete request to send to the server.
- In most cases, server-driven negotiation is used since this is much more efficient.

May 17, 2019 385 / 440

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

Negotiation Example

• The following is an example of typical negotiation header lines: Accept: text/xml, application/xml, text/html;q=0.9, text/plain;q=0.8 Accept-Language: de, en;q=0.5 Accept-Encoding: gzip, deflate, compress;q=0.9 Accept-Charset: ISO-8859-1, utf8;q=0.66, *;q=0.33

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- The first line indicates that the client accepts text/xml, application/xml, and text/plain and that it prefers text/html over text/plain.
- The last line indicates that the client prefers ISO-8859-1 encoding (with preference 1), UTF8 encoding with preference 0.66 and any other encoding with preference 0.33.

May 17, 2019 386 / 440

Conditional Requests

- Clients can make conditional requests by including headers that qualify the conditions under which the request should be honored.
- Conditional requests can be used to avoid unnecessary requests (e.g., to validate cached data).
- Example: If-Modified-Since: Wed, 26 Nov 2003 23:21:08 +0100

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

• The server checks whether the document was changed after the date indicated by the header line and only processes the request if this is the case.

May 17, 2019 387 / 440

Entity Tags

- An entity tag (ETag) is an opaque identifier assigned by a web server to a specific version of a resource found at a URL.
- If the resource content at that URL ever changes, a new and different ETag is assigned.
- ETags can be quickly compared to determine whether two versions of a resource are the same.
- A client can send a conditional request using the If-None-Match header.
- Example: If-None-Match: "686897696a7c876b7e"
- ETags can be used like cookies for tracking users...

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 388 / 440

Some Extensions

- Patch Method (RFC 5789)
 - A method to apply partial modifications to a resource.
- Delta Encoding (RFC 3229)
 - A mechanism to request only the document changes relative to a specific version.
- Web Distributed Authoring (RFC 2518, RFC 3253)
 - An extension to the HTTP/1.1 protocol that allows clients to perform remote web content authoring operations.

May 17, 2019 389 / 440

• HTTP as a Substrate (RFC 3205)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- HTTP is sometimes used as a substrate for other application protocols (e.g., the Internet Printing Protocol).
- There are some pitfalls with this approach as documented in RFC 3205.

Section 47: HTTP 2.0

IRLS, URNS, URIS, IRIS

45 HTTP 1.1 Methods

46 HTTP 1.1 Features

47 HTTP 2.0

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 390 / 440

HTTP Evolution

- HTTP/1.0
 - separate TCP connection for every resource request
 - published as RFC 1945 in May 1996
- HTTP/1.1
 - persistent connections and pipelining
 - conditional requests
 - published in RFC 2068 in Jan 1997, revised as RFC 2616 in Jun 1999
 - modularized version published as RFCs 7230-7235 in Jun 2014
- HTTP/2
 - header compression (binary encoding)
 - multiplexing (avoiding head-of-line blocking)
 - server push into client caches
 - published as RFC 7540 in May 2015

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 391 / 440

Part XII Multimedia over the Internet

Section 48: Voice over IP

48 Voice over IP

- Real-time Transport Protocol (RTP)
- **55** Session Initiation Protocol (SIP)
- **51** Session Initiation Protocol (SIP)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 396 / 440

Voice over IP

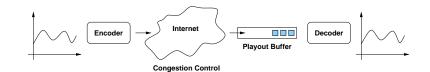

- Idea: Send voice over the packet switched Internet
 - Digitizing and encoding voice signals
 - Transmission over the Internet
 - Decoding and generating the analog voice signal
- UDP can be used for the transmission (why not TCP?)
- Need a protocol to take care of timing issues

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Need a common signalling protocol (ringing the phone)
- Need an infrastructure to locate users and phones
- Voice over IP has been very successful in replacing dedicated telephony technology

May 17, 2019 397 / 440

Voice over IP

• Voice quality is impacted by

Jürgen Schönwälder (Jacobs University Bremen)

- encoding of the digitized analog signal
- transmission impairments (delay, jitter, loss)
- Playout buffers can mitigate some of the effects
 - Playout buffers should be adaptive
 - For bidirectional voice conversations, there is an upper limit of delay

Computer Networks '2019

May 17, 2019 398 / 440

Pulse Code Modulation (PCM)

- Voice bandwidth is 4 kHz, so sampling bandwidth has to be 8 kHz (says Nyquist)
- Represent each sample with 8 bit (having 256 possible values).
- Required data rate is 8000 Hz * 8 bit = 64 kbps
- The traditional phone system was built on the notion of virtual circuits with data rates that are multipled of 64 kbit/s
- In real applications mu-law (North America) and a-law (Europe) variants are used, which code the analog signal on a logarithmic scale using 12 or 13 bits instead of 8 bits (see Standard ITU-T G.711).

There are many alternative codecs:

• Adaptive differential PCM (ADPCM), ITU-T G.726, encodes the difference between the actual and the previous voice packet, requiring only 32 kbps

May 17, 2019 399 / 440

- LD-CELP, Standard ITU-T G.728
- CS-ACELP, Standard ITU-T G.729 and G.729a

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- MP-MLQ, Standard ITU-T G.723.1, 6.3kbps, Truespeech
- ACELP, Standard ITU-T G.723.1, 5.3kbps, Truespeech
- LPC-10, able to reach 2.5 kbps
- iLBC, low bit-rate, able to deal with packet loss
- speex, free codec, 8/16/32 kHZ sampling

Section 49: Real-time Transport Protocol (RTP)

48 Voice over IP

- **50** Session Initiation Protocol (SIP)
- **51** Session Initiation Protocol (SIP)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 400 / 440

Real-time Transport Protocol (RTP)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- RTP provides end-to-end network transport functions suitable for applications transmitting real-time data, such as audio, video or simulation data, over multicast or unicast network services.
- RTP and RTCP are designed to be independent of the underlying transport and network layers (but commonly used over UDP).
- The protocol supports the use of RTP-level translators and mixers.

May 17, 2019 401 / 440

RTP Elements

- *Synchronisation Source*: A source identified by a 32-bit number which is originating data streams.
- *Mixer*: A component capable of resynchronizing streams, mixing reconstructed streams into a single stream, or translating the encoding of a stream (e.g., from a high-quality encoding to a low-bandwidth encoding).
- *Translator*: A component capable to translate streams in order to cross firewalls or different transports.
- *Receiver*: A component resynchronizing received streams, usually using playout buffers.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 402 / 440

RTP Message Format

		2 7 8 9 0 1 2 3 4 5 6 -+-+-+-+-+-+-+-+-+-+-++++++	
	PT I	sequence number	r l
timestamp			
synchronization source (SSRC) identifier			
contrib	uting source (C	SRC) identifiers	
+-			

- RTP is defined in RFC 3550.
- RTP supports multicasting of multimedia streams since it is running over UDP

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 403/440

RTP Message Header

- The V fied contains the RTP version number (current version is 2).
- The X bit indicates whether there are any extension headers
- The P bit indicates that there are padding bytes at the end of the packet. (The last padding byte contains the number of padding bytes.)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 404/440

- The CC field contains the number of CSRC identifiers.
- The M bit may be used by profiles that mark certain bytes in the packets.
- The PT identifies the format of the RTP payload.

RTP Message Header

- The sequence number field contains a sequence number for each packet.
- The timestamp field indicates the relative time of the packet in the overall media stream (media timestamp).
- The SSRC field identifies the synchronization source.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

• The CSRC identifiers (if present) identify the additional synchronization sources in cases where multiple media streams have been mixed into a single stream.

May 17, 2019 405 / 440

• RTP profiles define how RTP is used to transport specific codecs.

RTP Control Protocol (RTCP)

- RTCP allows senders and receivers to transmit a series of reports to one another that contain additional information about
 - the data being transmitted and
 - the performance of the network.
- RTCP packet types:
 - SR: Sender report, for transmission and reception statistics from participants that are active senders
 - RR: Receiver report, for reception statistics from participants that are not active senders
 - SDES: Source description items, including CNAME
 - BYE: Indicates end of participation
 - APP: Application-specific functions

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 406 / 440

388

RTCP Extended Reports (XR)

- XR packets convey information beyond that already contained in the reception report blocks of RTCP's sender report (SR) or Receiver Report (RR) packets.
- Packet-by-packet report blocks:

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Loss RLE Report Block: Run length encoding of reports concerning the losses and receipts of RTP packets.
- *Duplicate RLE Report Block*: Run length encoding of reports concerning duplicates of received RTP packets.
- Packet Receipt Times Report Block: A list of reception timestamps of RTP packets.

May 17, 2019 407 / 440

RTCP Extended Reports (XR)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- Reference time report blocks:
 - *Receiver Reference Time Report Block*: Receiver-end wallclock timestamps. Together with the DLRR Report Block mentioned next, these allow non-senders to calculate round-trip times.
 - *DLRR Report Block*: The delay since the last Receiver Reference Time Report Block was received.
- Metric report blocks:
 - *Statistics Summary Report Block*: Statistics on RTP packet sequence numbers, losses, duplicates, jitter, and TTL or Hop Limit values.
 - VoIP Metrics Report Block: Metrics for monitoring Voice over IP (VoIP) calls.

May 17, 2019 408 / 440

Section 50: Session Initiation Protocol (SIP)

- 48 Voice over IP
- Real-time Transport Protocol (RTP)
- **Session Initiation Protocol (SIP)**
- **51** Session Initiation Protocol (SIP)

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 409 / 440

Session Initiation Protocol (SIP)

- An application layer control (signaling) protocol for creating, modifying, and terminating sessions with one or more participants.
- Sessions include Internet telephone calls, multimedia distribution, and multimedia conferences.
- SIP makes use of elements called proxy servers to help route requests to the user's current location, authenticate and authorize users for services, implement provider call-routing policies, and provide features to users.

May 17, 2019 410 / 440

• SIP runs on top of several different transport protocols.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

• SIP is defined in RFC 3261.

SIP Facets

- User location: determination of the end system to be used for communication
- *User availability*: determination of the willingness of the called party to engage in communications
- User capabilities: determination of the media and media parameters to be used
- Session setup: "ringing", establishment of session parameters at both called and calling party
- *Session management*: including transfer and termination of sessions, modifying session parameters, and invoking services

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 411 / 440

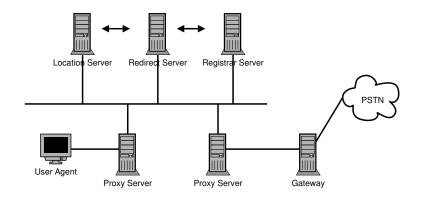

SIP Properties

- HTTP-like textual message format
- HTTP-like method calls and status responses
- Utilizes the Session Description Protocol (SDP) for the description of multimedia sessions
- User agents can initiate and receive calls (session endpoints)
- Proxy server provide an infrastructure to help user agents to establish sessions

• ...

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 412 / 440

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 416/440

SIP URIs

sip:user:password@host:port;uri-parameters?headers

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

- The user token identifies a particular resource at the host being addressed.
- The password token is a password associated with user (usage not recommended).
- The host token identifies the host providing SIP resources.
- The port number is the port to which a request is to be sent.
- The uri-parameters affect the request constructed from the URI.
- The headers token specifies the header fields to be included in a request constructed from a URI.

May 17, 2019 417 / 440

SIP URI Examples

• Typical SIP URI for user alice:

sip:alice@atlanta.com

• The same with an explicit IP address:

sip:alice@192.0.2.4

- The same with a password and an explicit transport:
- sip:alice:secretword@atlanta.com;transport=tcp
- SIP URI with an embedded PSTN phone number:

sip:+1-212-555-1212:1234@gateway.com;user=phone

• SIP URI with an explicit method call:

sip:atlanta.com;method=REGISTER?to=alice%40atlanta.com

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 418 / 440

Locating SIP Servers (RFC 3263)

- Given a SIP URI, how do you find the responsible SIP server?
- Need to determine
 - the transport protocol and
 - the IP address and port number
 - of the SIP server or proxy.
- In the general case, it is preferrable to have SIP URIs that belong to a domain rather than a specific host:
 - sip:j.schoenwaelder@jacobs-university.de
- A mechanism similar to MX records for email is needed.
- Could there be a generalized solution?

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

May 17, 2019 419 / 440

SIP Methods

- INVITE
 - Invites a user to participate in a session (call).
- ACK
 - Confirms final response to an INVITE request.
- OPTIONS
 - Used to query the capabilities of a server.
- BYE
 - Indicates termination of a call.
- CANCEL
 - Cancels a pending request.
- REGISTER
 - Registers a user agent at a proxy.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 420/440

SIP Status Codes

- 1xx Provisional request received, continuing to process the request
- 2xx Success the action was successfully received, understood, and accepted
- 3xx Redirection further action needs to be taken in order to complete the request
- 4xx Client Error the request contains bad syntax or cannot be fulfilled at this server

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 421/440

- 5xx Server Error the server failed to fulfill an apparently valid request
- 6xx Global Failure the request cannot be fulfilled at any server

SIP Communication Establishment

- Communication establishment is done in six steps:
 - 1. Registering, initiating and locating the user.
 - 2. Determine the media to use involves delivering a description of the session that the user is invited to.
 - 3. Determine the willingness of the called party to communicate.
 - 4. Call setup.
 - 5. Call modification of handling example, call transfer (opional)
 - 6. Call termination

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 422 / 440

SIP Registration

- During startup, a SIP user agent registers with its proxy/registration server.
- Registration can also occur when the SIP user agent moves and the new location needs to be communicated.
- The registration information is periodically refreshed (each SIP user agent has to re-register).
- Typically, the proxy/registration server will forward the location information to the location/redirect server.

May 17, 2019 423 / 440

• In many cases, the different servers might be co-located.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

ENUM (RFC 3761)

- ENUM defined in RFC 3761 provides a mechanism to lookup information associated with telephone numbers in the DNS.
- Number conversion:
 - 1. Remove all characters with the exception of the digits. Example: "+442079460148" \longrightarrow "442079460148"
 - 2. Put dots (".") between each digit. Example: 4.4.2.0.7.9.4.6.0.1.4.8
 - 3. Reverse the order of the digits. Example: 8.4.1.0.6.4.9.7.0.2.4.4
 - 4. Append the string ".e164.arpa" to the end. Example: 8.4.1.0.6.4.9.7.0.2.4.4.e164.arpa
- Lookup a NAPTR record for the resulting DNS name.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019 May 17, 2019 424 / 440

Session Description Protocol (SDP)

- SDP as defined in RFC 4566 is intended for describing multimedia sessions for the purposes of session announcement, session invitation, and other forms of multimedia session initiation.
- The SDP description format is used by other protocols (such as RSTP).
- A session description includes:
 - Session name and purpose
 - Time(s) the session is active
 - The media comprising the session

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

• Information needed to receive the media streams (addresses, ports, formats and so on)

May 17, 2019 425 / 440

Sample Session Description

v=0 o=mhandley 2890844526 2890842807 IN IP4 126.16.64.4 s=SDP Seminar i=A Seminar on the session description protocol u=http://www.cs.ucl.ac.uk/staff/M.Handley/sdp.03.ps e=mjh@isi.edu (Mark Handley) c=IN IP4 224.2.17.12/127 t=2873397496 2873404696 a=recvonly m=audio 49170 RTP/AVP 0 m=vuideo 51372 RTP/AVP 0 m=vuideo 51372 RTP/AVP 31 m=application 32416 udp wb a=orient:portrait

• Description of a session called "SDP Seminar" which is sent to the multicast group 224.2.17.12 and contains three channels (audio, video, whiteboard).

May 17, 2019 426 / 440

• Start and stop times are indicated in the t= field.

Jürgen Schönwälder (Jacobs University Bremen) Computer Networks '2019

Part XIII Summary Tables

This appendix contains some summary tables that make it easier to compare some protocols or to quickly lookup how certain things are solved by a certain protocol.

Aspect	Ethernet (+ VLANs)	IP version 4	IP version 6
Layers	physical (1) and data link (2)	network (3)	network (3)
Addresses	48-bit	32-bit	128-bit (64-bit interface identifiers)
Assignment	static (vendor)	manual or dynamic	manual or dynamic
Auto Configuration	auto negotiation (802.3u)	DHCPv4 (address)	DHCPv6 (address) or SLAC (prefix)
Header	fixed length	variable length	fixed length + header chain
Checksum	CRC-32	Interent checksum (header)	none (trust other layers)
Forwarding	exact lookup and flooding	longest prefix match	longest prefix match
Routing	backward learning + spanning tree	OSPF, BGP,	OSPF, BGP,
Tagging	VLANs (802.1Q)		Flow Label
Priorities	3 priority bits (801.1Q)	6-bit DSCP (Type of Service field)	6-bit DSCP (Traffic Class field)
Error Reporting	none	ICMPv4	ICMPv6
Testing	none	ICMPv4 (ping / traceroute)	ICMPv6 (ping / traceroute)
Adress Mapping	not applicable	ARP	ICMPv6 (neighbor discovery)
Fragmentation		routers on the path	sender only
PMTU discovery		optional but recommended	mandatory if MTU > 1280
Security	lacking	lacking	possible (AH, ESP), not widely used

ls) and IPv4 and IPv6
(+ VLANs)
of Ethernet
comparison of
Table 1: C

UDP TCP SCTP DCCP	yes yes yes	Table 2: Comparison of UDP, TCP, SCTP, and DCCP

nD	ou	son of L
Aspect	congestion aware no	Table 2: Comparis

Aspect	RIP	OSPF	BGP
Algorithm	Bellman Ford	Dijkstra	
Class	distance vector routing	link state routing	path vector routing
Usage	IGP	IGP	EGP
Scalability	limited	areas	
Transport			
Security			

Table 3: Comparison of Internet Routing Protocols
